(54) Title: MINIMAL PROMOTERS AND USES THEREOF

GMT of Anti-HBsAg Antibodies (mIU/ml) At Six Weeks Post-Prime (Four Experiments @ 8 Mice per Group)

(57) Abstract

Minimal promoter sequences are described. Reagents including a nucleic acid molecule which contains these minimal promoter sequences are also described. Methods for constructing these reagents, and methods for using these reagents are also described.

MINIMAL PROMOTERS AND USES THEREOF

Technical Field

The invention relates to the general fields of molecular biology and immunology, and generally relates to reagents useful in nucleic acid immunization techniques. More specifically, the invention relates to truncated forms of transcriptional promoter elements, nucleic acid molecules containing such promoter elements, and to the use of reagents containing such nucleic acid molecules for nucleic acid immunization and gene therapy.

10

Background

Techniques for the injection of DNA and mRNA into mammalian tissue for the purposes of immunization against an expression product have been described in the art. See, e.g., European Patent Specification EP 0 500 799 and U.S. Patent No. 5,589,466. The techniques, termed "nucleic acid immunization" herein, have been shown to elicit both humoral and cell-mediated immune responses. For example, sera from mice immunized with a DNA construct encoding the envelope glycoprotein, gp160, were shown to react with recombinant gp160 in immunoassays, and lymphocytes from the injected mice were shown to proliferate in response to recombinant gp120. Wang et al. (1993) *Proc. Natl. Acad. Sci. USA* 90:4156-4160. Similarly, mice immunized with a human growth hormone (hGH) gene demonstrated an antibody-based immune response. Tang et al. (1992) *Nature* 356:152-154. Intramuscular injection of DNA encoding influenza nucleoprotein driven by a mammalian promoter has been shown to elicit a CD8+ CTL response that can protect mice against subsequent lethal challenge with virus. Ulmer et al. (1993) *Science* 259:1745-1749. Immunohistochemical studies of the injection site revealed that the DNA was taken up by myeloblasts, and cytoplasmic production of viral protein could be demonstrated for at least 6 months.

It has been a major aim of artisans practising in the fields of gene therapy and nucleic acid immunization to identify and design expression systems that provide as high a level of production as possible for a gene or sequence of interest that has been delivered into a host cell. High level production is seen as being a necessary

-2-

prerequisite for any expression system used in gene therapy (to provide for sufficient levels of a therapeutic gene product) or nucleic acid immunization (to provide for a sufficient immune response against an encoded antigen product). Several factors are known to affect the level of production attainable from such transfected host cells,

5 including transfection efficiency (e.g., the copy number in the cell) and the efficiency with which the gene or sequence of interest is transcribed and the mRNA translated.

Accordingly, a number of expression systems have been described in the art, each of which typically consists of a vector containing a gene or nucleotide sequence of interest operably linked to expression control sequences which control the

10 expression of the gene or nucleotide sequence. These control sequences include transcriptional promoter sequences and transcriptional start and termination sequences. Transcriptional promoter sequences are generally located just upstream of initiation sites for RNA transcripts, and include a "TATA" box and a "CAAT" box, respectively located about 30 and 80 nucleotides upstream (e.g., at about the -30

15 and -80 position) relative to the initiation site. Corden et al. (1980) *Science* 209:1406-1414; Chambon, P. (1981) *Ann. Rev. Biochem.* 50:349-383. Commonly used promoters for mammalian cell expression systems include the SV40 early promoter, a CMV promoter such as the CMV immediate early promoter (Chapman et al. (1991) *Nucl. Acids Res.* 19:3979-3986), the mouse mammary tumor virus LTR

20 promoter, the adenovirus major late promoter (Ad MLP), and the herpes simplex virus promoter, among others. Nonviral promoters, such as a promoter derived from the murine metallothionein gene, are also commonly used for such expression systems. These promoter systems are normally selected to provide for the highest level of expression possible for a given sequence.

25 A number of transcriptional modulator elements that are found more than 110 nucleotides upstream (-110) of various genes have also been commonly used in the art. These upstream sequences are deemed essential for the expression of early genes in simian, murine and human DNA viruses, and are commonly referred to as "enhancers." Enhancers are broadly defined as a cis-acting agent which, when

30 operably linked to a promoter/gene sequence, will dramatically increase transcription of that gene sequence. Enhancers can function from positions that are much further away from a sequence of interest than other expression control elements (e.g.,

-3-

promoters), and can operate when positioned in either orientation relative to the sequence of interest. Banerji et al. (1981) *Cell* 27:299-308, deVilleirs et al. (1981) *Nucleic Acids Research* 9:6251-6264. Enhancers have been identified from a number of viral sources, including polyoma virus, BK virus, cytomegalovirus (CMV), adenovirus, simian virus 40 (SV40), Moloney sarcoma virus, bovine papilloma virus, and Rous sarcoma virus (deVilleirs et al. *supra*, Rosenthal et al. (1983) *Science* 222:749-755, Hearing et al. (1983) *Cell* 33:695-703, Weeks et al. (1983) *Mol. Cell. Biol.* 3:1222-1234, Levinson et al. (1982) *Nature* 295:568-572, and Luciw et al. (1983) *Cell* 33:705-716. These enhancer elements are often coupled with homologous and heterologous promoter sequences to provide enhancer/promoter pairs for use in expression systems. However, probably the most frequently used enhancer/promoter pair used in gene therapy and nucleic acid immunization is the hCMV immediate-early enhancer/promoter pair. See e.g., U.S. Patent Nos. 5,168,062 and 5,385,839 to Stinski, and EP Patent Specification 0 323 997 B1. The hCMV enhancer element has also been used without the hCMV promoter element, for example to modulate a heterologous promoter sequence. See e.g., EP Patent Specification 0 173 177 B1. The hCMV immediate-early enhancer/promoter pair provides for robust expression from a variety of different sequences of interest, and this high level expression is commonly thought of as establishing the “gold standard” for any given expression system.

Summary of the Invention

It is a primary object of the invention to provide a promoter system which provides a better expression character in mammalian cells, particularly *in vivo*. It has now surprisingly been found that the use of a promoter sequence that normally is paired with its homologous enhancer sequence in an expression system will provide for a greatly enhanced immune response against an encoded antigen when the promoter is used in a truncated, enhancer-less form in an expression system. The “enhancerless” promoter sequence is referred to herein as a “minimal promoter.” An improved immunological response to a nucleic acid vaccine composition which incorporates the promoter system can be achieved. More efficient gene therapy may also be achieved.

-4-

Accordingly, the present invention provides use of a nucleic acid construct comprising a minimal promoter sequence operably linked to a coding sequence encoding a polypeptide of interest in the manufacture of a medicament for use in obtaining expression in mammalian cells of the said polypeptide. The invention also

5 provides:

- a method of obtaining expression in mammalian cells of a polypeptide of interest, which method comprises transferring into said cells a nucleic acid construct comprising a minimal promoter sequence operably linked to a coding sequence for the said polypeptide;
- 10 - coated particles suitable for use in particle-mediated nucleic acid immunisation, which particles comprise carrier particles coated with a nucleic acid construct comprising a minimal promoter sequence operably linked to a coding sequence encoding an antigen;
- a particle acceleration device suitable for particle-mediated nucleic
- 15 acid immunisation, the said device being loaded with coated particles of the invention;
- a purified, isolated minimal promoter sequence; and
- a nucleic acid construct comprising a minimal promoter sequence operably linked to a coding sequence

20 The nucleic acid construct may be present in a vector construct, for example in a plasmid vector or in a recombinant viral vector. A nucleic acid immunization reagent capable of eliciting an immune response against an antigen of interest is thus provided, the reagent comprising a nucleic acid construct which includes a nucleic acid sequence of interest under the transcriptional control of a minimal promoter

25 sequence. Expression systems can be constructed for use in nucleic acid immunization to provide for a greatly enhanced immune response against an antigen of interest.

These and other objects, aspects, embodiments and advantages of the present invention will readily occur to those of ordinary skill in the art in view of the

30 disclosure herein.

Brief Description of the Figures

Figure 1 depicts a comparison between the minimal promoter constructs of the present invention and their corresponding enhanced promoter constructs. The *in vivo* performance of the promoter constructs was assessed by measuring antibody

5 production against the antigen of interest in animals receiving nucleic acid immunization with the constructs.

Figure 2 depicts a comparison between a minimal human cytomegalovirus (hCMV) promoter construct produced according to the present invention, and its

10 corresponding, fully enhanced hCMV promoter construct.

Figures 3 and 4 also depict comparison results obtained from *in vivo* vaccination studies using the minimal promoter constructs of the present invention and their corresponding enhanced promoter constructs. Here again, the *in vivo*

15 performance of the promoter constructs was assessed by measuring antibody production against the antigen of interest in animals receiving nucleic acid immunization with the constructs.

Detailed Description of the Preferred Embodiments

20 Before describing the present invention in detail, it is to be understood that this invention is not limited to particularly exemplified molecules or process parameters as such may, of course, vary. It is also to be understood that the terminology used herein is for the purpose of describing particular embodiments of the invention only, and is not intended to be limiting. In addition, the practice of the

25 present invention will employ, unless otherwise indicated, conventional methods of virology, microbiology, molecular biology, recombinant DNA techniques and immunology all of which are within the ordinary skill of the art. Such techniques are explained fully in the literature. See, e.g., Sambrook, et al., *Molecular Cloning: A Laboratory Manual* (2nd Edition, 1989); *DNA Cloning: A Practical Approach*, vol.

30 I & II (D. Glover, ed.); *Oligonucleotide Synthesis* (N. Gait, ed., 1984); *A Practical Guide to Molecular Cloning* (1984); and *Fundamental Virology*, 2nd Edition, vol. I & II (B.N. Fields and D.M. Knipe, eds.).

All publications, patents and patent applications cited herein, whether *supra* or *infra*, are hereby incorporated by reference in their entirety.

It must be noted that, as used in this specification and the appended claims, the singular forms "a," "an" and "the" include plural referents unless the content

5 clearly dictates otherwise.

A. Definitions

Unless defined otherwise, all technical and scientific terms used herein have the same meaning as commonly understood by one of ordinary skill in the art to

10 which the invention pertains. Although a number of methods and materials similar or equivalent to those described herein can be used in the practice of the present invention, the preferred materials and methods are described herein.

In describing the present invention, the following terms will be employed, and are intended to be defined as indicated below.

15 The term "nucleic acid immunization" is used herein to refer to the introduction of a nucleic acid molecule encoding one or more selected antigens into a host cell for the *in vivo* expression of the antigen or antigens. The nucleic acid molecule can be introduced directly into the recipient subject, such as by injection; transdermal particle delivery; inhalation; topically, or by oral, intranasal or mucosal
20 modes of administration. The molecule alternatively can be introduced *ex vivo* into cells which have been removed from a subject. In this latter case, the cells are reintroduced into the subject where an immune response can be mounted against the antigen encoded by the nucleic acid molecule.

An "antigen" refers to any agent, generally a macromolecule, which can elicit
25 an immunological response in an individual. The term may be used to refer to an individual macromolecule or to a homogeneous or heterogeneous population of antigenic macromolecules. As used herein, "antigen" is generally used to refer to a protein molecule or portion thereof which comprises one or more epitopes. For purposes of the present invention, antigens can be obtained or derived from any
30 known virus, bacteria, parasite or fungal pathogen. The term also intends any of the various tumor-specific antigens and antigens associated with autoimmune diseases. Furthermore, for purposes of the present invention, an "antigen" includes a protein

having modifications, such as deletions, additions and substitutions (generally conservative in nature) to the native sequence, so long as the protein maintains sufficient immunogenicity. These modifications may be deliberate, for example through site-directed mutagenesis, or may be accidental, such as through mutations
5 of hosts which produce the antigens.

In various aspects of the invention, the antigen contains one or more T cell epitopes. A "T cell epitope" refers generally to those features of a peptide structure which are capable of inducing a T cell response. In this regard, it is accepted in the art that T cell epitopes comprise linear peptide determinants that assume extended
10 conformations within the peptide-binding cleft of MHC molecules, (Unanue et al. (1987) *Science* 236:551-557). As used herein, a T cell epitope is generally a peptide having at least about 3-5 amino acid residues, and preferably at least 5-10 or more amino acid residues. The ability of a particular antigen to stimulate a cell-mediated immunological response may be determined by a number of well-known assays, such
15 as by lymphoproliferation (lymphocyte activation) assays, CTL cytotoxic cell assays, or by assaying for T-lymphocytes specific for the antigen in a sensitized subject. See, e.g., Erickson et al. (1993) *J. Immunol.* 151:4189-4199; and Doe et al. (1994) *Eur. J. Immunol.* 24:2369-2376.

In other aspects of the invention, the antigen contains one or more B cell epitopes. A "B cell epitope" generally refers to the site on an antigen to which a specific antibody molecule binds. The identification of epitopes which are able to elicit an antibody response is readily accomplished using techniques well known in the art. See, e.g., Geysen et al. (1984) *Proc. Natl. Acad. Sci. USA* 81:3998-4002 (general method of rapidly synthesizing peptides to determine the location of
20 immunogenic epitopes in a given antigen); U.S. Patent No. 4,708,871 (procedures for identifying and chemically synthesizing epitopes of antigens); and Geysen et al. (1986) *Molecular Immunology* 23:709-715 (technique for identifying peptides with
25 high affinity for a given antibody).

An "immune response" against an antigen of interest is the development in an
30 individual of a humoral and/or a cellular immune response to that antigen. For purposes of the present invention, a "humoral immune response" refers to an immune response mediated by antibody molecules, while a "cellular immune response" is one

mediated by T-lymphocytes and/or other white blood cells.

A "coding sequence", or a sequence which "encodes" a polypeptide, is a nucleic acid molecule which is transcribed (in the case of DNA) and translated (in the case of mRNA) into a polypeptide *in vivo* when placed under the control of appropriate regulatory sequences. The boundaries of the coding sequence are determined by a start codon at the 5' (amino) terminus and a translation stop codon at the 3' (carboxy) terminus. For the purposes of the invention, a coding sequence can include, but is not limited to, cDNA from viral, procaryotic or eucaryotic mRNA, genomic DNA sequences from viral or procaryotic DNA, and even synthetic DNA sequences. A transcription termination sequence may be located 3' to the coding sequence.

A "nucleic acid" molecule can include, but is not limited to, procaryotic sequences, eucaryotic mRNA, cDNA from eucaryotic mRNA, genomic DNA sequences from eucaryotic (e.g., mammalian) DNA, and even synthetic DNA sequences. The term also captures sequences that include any of the known base analogs of DNA and RNA.

"Operably linked" refers to an arrangement of elements wherein the components so described are configured so as to perform their usual function. Thus, a given promoter operably linked to a coding sequence is capable of effecting the expression of the coding sequence when the proper enzymes are present. The promoter need not be contiguous with the coding sequence, so long as it functions to direct the expression thereof. Thus, for example, intervening untranslated yet transcribed sequences can be present between the promoter sequence and the coding sequence and the promoter sequence can still be considered "operably linked" to the coding sequence.

"Recombinant" as used herein to describe a nucleic acid molecule means a polynucleotide of genomic, cDNA, semisynthetic, or synthetic origin which, by virtue of its origin or manipulation: (1) is not associated with all or a portion of the polynucleotide with which it is associated in nature; and/or (2) is linked to a polynucleotide other than that to which it is linked in nature.

Two nucleic acid sequences are "substantially homologous" when at least about 70%, preferably at least about 80-90%, and most preferably at least about 95%,

-9-

of the nucleotides match over a defined length of the molecule. As used herein, substantially homologous also refers to sequences showing identity to the specified nucleic acid. Nucleic acid sequences that are substantially homologous can be identified in a Southern hybridization experiment under, for example, stringent
5 conditions, as defined for that particular system. Defining appropriate hybridization conditions is within the skill of the art. See, e.g., Sambrook et al., *supra*; *DNA Cloning*, vols I & II, *supra*; *Nucleic Acid Hybridization*, *supra*. Such sequences can also be confirmed and further characterized by direct sequencing of PCR products.

The terms "individual" and "subject" are used interchangeably herein to refer
10 to any member of the subphylum cordata, including, without limitation, humans and other primates, including non-human primates such as chimpanzees and other apes and monkey species; farm animals such as cattle, sheep, pigs, goats and horses; domestic mammals such as dogs and cats; laboratory animals including rodents such as mice, rats and guinea pigs; birds, including domestic, wild and game birds such as
15 chickens, turkeys and other gallinaceous birds, ducks, geese, and the like. The terms do not denote a particular age. Thus, both adult and newborn individuals are intended to be covered. The methods described herein are intended for use in any of the above vertebrate species, since the immune systems of all of these vertebrates operate similarly.

20

B. General Methods

A minimal promoter is used in the present invention. The minimal promoter sequence is generally derived from a DNA virus. Typically, the promoter is a promoter which is associated with an early viral gene and usually modulated by an
25 upstream or downstream enhancer element. The promoter sequence is used in its enhancerless form (i.e., it is not coupled with its native enhancer sequence when used in the context of the present invention, however, it may be used in a construct which contains other heterologous enhancer sequences). Thus, the minimal promoters of the present invention will typically be comprised of a nucleotide sequence of about
30 130 bases or less, which sequence will correspond to the sequence spanning positions -1 to about -130 relative to the start of RNA synthesis of the native viral early gene.

In preferred embodiments, the minimal promoter is obtained or derived from

-10-

a member of the Herpesvirus family of viruses. In particular embodiments, the minimal promoter consists essentially of an enhancerless promoter sequence from a simian, murine or human CMV virus (for example, the sCMV or hCMV immediate early promoter), an enhancerless promoter sequence from a RSV virus, an

5 enhancerless promoter sequence from a pseudorabies virus (PRV) such as the PRV early promoter region, or a functional variant thereof. The minimal promoter sequence may therefore consist essentially of a human cytomegalovirus (hCMV) immediate early promoter sequence, a pseudorabies virus (PRV) early promoter region, a simian cytomegalovirus (sCMV) immediate early promoter sequence or a

10 functional variant thereof.

A functional variant sequence may vary from a native promoter sequence by one or more base substitutions, deletions or insertions. There may be from 1 to 30, for example from 5 to 20, base substitutions and/or from 1 to 30, for example from 5 to 20, base deletions and/or from 1 to 30, for example 5 to 20, base insertions.

15 Functional fragments of a native promoter sequence may be used.

Variant sequences can readily be constructed by routine methodologies such as site-directed mutagenesis. The ability of a variant sequence to act as a promoter and thus retain function can be determined by experimentation. A variant sequence can be coupled to a reporter gene in a suitable expression system and the presence or

20 absence of expression determined. The present invention is particularly applicable to humans, so the ability of a variant sequence to drive expression *in vitro* in a human cell line may be examined.

The minimal promoter sequence is coupled with a heterologous nucleotide sequence of interest, typically a full gene when used in the context of gene therapy or

25 a coding sequence for an antigen when used in the context of nucleic acid immunization. In the case of gene therapy, the nucleotide sequence of interest encodes a protein whose expression confers benefits on the subject under treatment. A genetic defect can thus be compensated for. The coding sequence may encode a therapeutic protein.

30 The protein may be a blood protein, such as a clotting protein (e.g. kinogen, prothrombin, fibrinogen factor VII, factor VIII or factor IX). The protein may be an enzyme, such as a catabolic or anabolic enzyme. The enzyme may be a gastro-

-11-

intestinal enzyme, metabolic (e.g. glycolysis or Krebs cycle) enzyme or a cell signalling enzyme . The enzyme may make, breakdown or modify lipids, fatty acids, glycogen, amino acids, proteins, nucleotides, polynucleotides (e.g. DNA or RNA) or carbohydrate (e.g. sugars), and thus may typically be a protease, lipase or

5 carbohydrase. The enzyme may be a protein modifying enzyme, such as an enzyme that adds or takes chemical moieties from a protein (e.g. a kinase or phosphatase).

The protein may be a transport or binding protein (e.g. which binds and/or transports a vitamin, metal ion, amino acid or lipid, such as cholesterol ester transfer protein, phospholipid transfer protein or an HDL binding protein). The protein may

10 be a connective tissue protein (e.g. a collage, elastin or fibronectin), or a muscle protein (e.g. actin, myosin, dystrophin or mini-dystrophin). The protein may be a neuronal, liver, cardiac or adipocyte protein. The protein may be cytotoxic. The protein may be a cytochrome.

15 The protein may be able to cause the replication, growth or differentiation of cells. The protein may be development gene (e.g. which is expressed only before birth). The protein may be aid transcription or translation gene or may regulate transcription or translation (e.g. a transcription factor or a protein that binds a transcription factor or polymerase). The protein may be a signalling molecule, such as an intracellular or extracellular signalling molecule (e.g. a hormone).

20 The protein may be an immune system gene, such as an antibody, T cell receptor, MHC molecule, cytokine (e.g IL-1, IL-2, IL-3, IL-4, IL-5, IL-6, IL-7, IL-8, IL-10, IL-10, TNF- α , TNF- β , TGF- β), an interferon (e.g. IFN- α , IFN- β , IFN- γ), chemokine (e.g. MIP-1 α , MIP-1 β , RANTES), an immune receptor (e.g. a receptor for a cytokine, interferon or chemokine, such as receptor for any of the above-mentioned cytokines, interferons or chemokines), a cell surface marker (e.g. macrophage, T cell, B cell, NK cell or dendritic cell surface marker)(eg. CD 1, 2, 3, 4, 5, 6, 7, 8, , 16, 18, , 19, 28, 40, or 45; or a natural ligand thereof) or a complement gene.

30 The protein may be a trophic factor (e.g. BDNF, CNTF, NGF, IGF, GMF, aFGF, bFGF, VEGF, NT3, T5, HARP) or an apolipoprotein. The protein may be a tumour suppressor genes (e.g. p53, Rb, Rap1A, DCC or k-rev) or a suicide gene (thymidine kinase or cytosine deaminase).

-12-

When used in reagents for nucleic acid immunization, the minimal promoter will be operably linked to a coding sequence which encodes an antigen of interest. The antigen of interest will preferably be associated with a pathogen, such as a viral, bacterial or parasitic pathogen, or the antigen may be a tumor-specific antigen. The 5 antigen may be a full length protein. Alternatively, the antigen may just consist essentially of a B-cell epitope or a T-cell epitope of an antigen.

Tumor-specific antigens include, but are not limited to, any of the various MAGEs (melanoma associated antigen E), including MAGE 1, MAGE 2, MAGE 3 (HLA-A1 peptide), MAGE 4, etc.; any of the various tyrosinases (HLA-A2 peptide); 10 mutant ras; mutant p53; and p97 melanoma antigen. Other tumor-specific antigens include the Ras peptide and p53 peptide associated with advanced cancers, the HPV 16/18 and E6/E7 antigens associated with cervical cancers, MUC1-KLH antigen associated with breast carcinoma, CEA (carcinoembryonic antigen) associated with colorectal cancer, gp100 or MART1 antigens associated with melanoma, and the 15 PSA antigen associated with prostate cancer. The *p53* gene sequence is known (see e.g., Harris et al. (1986) *Mol. Cell. Biol.* 6:4650-4656) and is deposited with GenBank under Accession No. M14694.

Suitable viral antigens include, but are not limited to, polynucleotide sequences encoding antigens from the hepatitis family of viruses, including hepatitis 20 A virus (HAV), hepatitis B virus (HBV), hepatitis C virus (HCV), the delta hepatitis virus (HDV), hepatitis E virus (HEV) and hepatitis G virus (HGV). By way of example, the viral genomic sequence of HBV is known, as are methods for obtaining antigen-encoding sequences therefrom. See, e.g., Ganem et al. (1987) *Annu. Rev. Biochem.* 56:651-693; Hollinger, F.B. (1990) *Hepatitis B virus*, vol. II, pp.2171-25, in Fields et al. (eds), *Virology*, 2nd ed, Raven Press, New York, NY; and Valenzuela et al. (1980) *The nucleotide Sequence of the Hepatitis B viral Genome and the Identification of the Major Viral Genes*, pp. 57-70, in Fields et al. (eds), *Animal Virus Genetics*, Academic Press, New York, NY). The HBV genome encodes several viral proteins, including the large, middle and major surface antigen 30 polypeptides, the X-gene polypeptide, and the core polypeptide. See, e.g., Yokosuka et al. (1986) *N. Engl. J. Med.* 315:1187-1192; Imazeki et al. (1987) *Hepatology* 7:753-757; Kaneko et al. (1988) *J. Virol.* 62:3979-3984; and Ou et al. (1990) *J.*

-13-

Virol. 64:4578-4581. In like manner, the viral genomic sequence of HCV is known, as are methods for obtaining the sequence. See, e.g., International Publication Nos. WO 89/04669; WO 90/11089; and WO 90/14436. The HCV genome encodes several viral proteins, including E1 and E2. See, e.g., Houghton et al. (1991)

5 *Hepatology* 14:381-388. The sequences encoding these HBV and HCV proteins, as well as antigenic fragments thereof, will find use in the present methods. Similarly, the coding sequence for the δ-antigen from HDV is known (see, e.g., U.S. Patent No. 5,378,814).

In like manner, sequences encoding a wide variety of protein antigens from 10 the herpesvirus family can be used in the present invention, including antigens derived from herpes simplex virus (HSV) types 1 and 2, such as HSV-1 and HSV-2 glycoproteins gB, gD and gH; antigens from varicella zoster virus (VZV), Epstein-Barr virus (EBV) and cytomegalovirus (CMV) including CMV gB and gH; and antigens from other human herpesviruses such as HHV6 and HHV7. (See, e.g. Chee 15 et al. (1990) *Cytomegaloviruses* (J.K. McDougall, ed., Springer-Verlag, pp. 125-169; McGeoch et al. (1988) *J. Gen. Virol.* 69:1531-1574; U.S. Patent No. 5,171,568; Baer et al. (1984) *Nature* 310:207-211; and Davison et al. (1986) *J. Gen. Virol.* 67:1759-1816.)

HIV antigens, such as the gp120 sequences for a multitude of HIV-1 and 20 HIV-2 isolates, including members of the various genetic subtypes of HIV, are known and reported (see, e.g., Myers et al., Los Alamos Database, Los Alamos National Laboratory, Los Alamos, New Mexico (1992); and Modrow et al. (1987) *J. Virol.* 61:570-578) and antigens derived from any of these isolates will find use in the present methods. Furthermore, the invention is equally applicable to other 25 immunogenic moieties derived from any of the various HIV isolates, including any of the various envelope proteins such as gp160 and gp41, gag antigens such as p24gag and p55gag, as well as proteins derived from the *pol*, *env*, *tat*, *vif*, *rev*, *nef*, *vpr*, *vpu* and LTR regions of HIV.

Sequences encoding antigens derived or obtained from other viruses will also 30 find use in the claimed methods, such as without limitation, sequences from members of the families Picornaviridae (e.g., polioviruses, etc.); Caliciviridae; Togaviridae (e.g., rubella virus, dengue virus, etc.); Flaviviridae; Coronaviridae;

-14-

Reoviridae; Birnaviridae; Rhabdoviridae (e.g., rabies virus, etc.); Filoviridae; Paramyxoviridae (e.g., mumps virus, measles virus, respiratory syncytial virus, etc.); Bunyaviridae; Arenaviridae; Retroviridae (e.g., HTLV-I; HTLV-II; HIV-1 (also known as HTLV-III, LAV, ARV, hTLR, etc.)), including but not limited to antigens

5 from the isolates HIV_{IIIb}, HIV_{SF2}, HIV_{LAV}, HIV_{LA1}, HIV_{MN}); HIV-1_{CM235}, HIV-1_{US4}; HIV-2, among others. See, e.g. *Virology*, 3rd Edition (W.K. Joklik ed. 1988); *Fundamental Virology*, 2nd Edition (B.N. Fields and D.M. Knipe, eds. 1991), for a description of these and other viruses..

Sequences encoding suitable bacterial and parasitic antigens are obtained or

10 derived from known causative agents responsible for diseases such as Diphteria, Pertussis, Tetanus, Tuberculosis, Bacterial or Fungal Pneumonia, Cholera, Typhoid, Plague, Shigellosis or Salmonellosis, Legionaire's Disease, Lyme Disease, Leprosy, Malaria, Hookworm, Onchocerciasis, Schistosomiasis, Trypanosomiasis, Lesmaniasis, Giardia, Amoebiasis, Filariasis, Borelia, and Trichinosis. Still further

15 antigens can be obtained or derived from unconventional viruses or virus-like agents such as the causative agents of kuru, Creutzfeldt-Jakob disease (CJD), scrapie, transmissible mink encephalopathy, and chronic wasting diseases, or from proteinaceous infectious particles such as prions that are associated with mad cow disease.

20 Both the sequence for the minimal promoter and the coding sequence of interest can be obtained and/or prepared using known methods. For example, substantially pure antigen preparations can be obtained using standard molecular biological tools. That is, polynucleotide sequences coding for the above-described antigens can be obtained using recombinant methods, such as by screening cDNA and genomic libraries from cells expressing the gene, or by deriving the gene from a vector known to include the same. Furthermore, the desired gene or promoter sequence can be isolated directly from cells and tissues containing the same, using standard techniques, such as phenol extraction and PCR of cDNA or genomic DNA. See, e.g., Sambrook et al., *supra*, for a description of techniques used to obtain and

25 isolate DNA. Polynucleotide sequences can also be produced synthetically, rather than cloned.

30 Yet another convenient method for isolating specific nucleic acid molecules

is by the polymerase chain reaction (PCR). Mullis et al. (1987) *Methods Enzymol.* 155:335-350. This technique uses DNA polymerase, usually a thermostable DNA polymerase, to replicate a desired region of DNA. The region of DNA to be replicated is identified by oligonucleotides of specified sequence complementary to 5 opposite ends and opposite strands of the desired DNA to prime the replication reaction. The product of the first round of replication is itself a template for subsequent replication, thus repeated successive cycles of replication result in geometric amplification of the DNA fragment delimited by the primer pair used.

Once the sequences for the minimal promoter and the coding sequence of 10 interest have been obtained, they are operably linked together to provide a nucleic acid molecule using standard cloning or molecular biology techniques. See, e.g., Edge (1981) *Nature* 292:756; Nambair et al (1984) *Science* 223:1299; and Jay et al 91984) *J. Biol. Chem.* 259:6311. The nucleic acid molecule is then inserted into a suitable vector such as an expression plasmid or viral vector construct.

15 The nucleic acid construct comprising the minimal promoter and a selected coding sequence generally also comprises other control sequences. These other control sequences typically comprise a terminator and/or translation initiation sequence (e.g. GCCACCATGG or GCCCCCATGG) and/or translational stop codon (e.g. TAA, TAG or TGA) and/or polyadenylation signal and/or a RNA pause site.
20 The native enhancer for the promoter sequence is not present, however. Generally, no enhancer is present at all.

For gene therapy purposes, the nucleic acid construct is integrated into the genome of the cell into which it has been introduced. The nucleic acid construct may therefore also comprise a sequence which enhances integration of the construct, such 25 as the loxP sites of the bacteriophage P1 Cre recombination system, FRT sites of the yeast FLP recombination system or Adeno-associated virus (AAV) terminal repeat sequences.

Once complete, the constructs are used for gene therapy or nucleic acid immunization using standard gene delivery protocols. Methods for gene delivery are 30 known in the art. See, e.g., U.S. Patent Nos. 5,399,346, 5,580,859, 5,589,466. Genes can be delivered either directly to a subject or, alternatively, delivered *ex vivo*, to cells derived from the subject and the cells reimplanted in the subject.

-16-

A number of viral based systems have been developed for gene transfer into mammalian cells. For example, a selected coding sequence can be inserted into a vector and packaged in retroviral particles using techniques known in the art. The recombinant virus can then be isolated and delivered to cells of the subject either *in vivo* or *ex vivo*. A number of retroviral systems have been described (U.S. Patent No. 5,219,740; Miller et al. (1989) *BioTechniques* 7:980-990; Miller, A.D. (1990) *Human Gene Therapy* 1:5-14; and Burns et al. (1993) *Proc. Natl. Acad. Sci. USA* 90:8033-8037.

A number of adenovirus vectors have also been described (Haj-Ahmad et al. 10 (1986) *J. Virol.* 57:267-274; Bett et al. (1993) *J. Virol.* 67:5911-5921; Mittereder et al. (1994) *Human Gene Therapy* 5:717-729; and Rich et al. (1993) *Human Gene Therapy* 4:461-476). Additionally, various adeno-associated virus (AAV) vector systems have been developed for gene delivery. AAV vectors can be readily constructed using techniques well known in the art. See, e.g., U.S. Patent Nos. 15 5,173,414 and 5,139,941; International Publication Nos. WO 92/01070 (published 23 January 1992) and WO 93/03769 (published 4 March 1993); Lebkowski et al. (1988) *Molec. Cell. Biol.* 8:3988-3996; Vincent et al. (1990) *Vaccines* 90 (Cold Spring Harbor Laboratory Press); Carter, B.J. (1992) *Current Opinion in Biotechnology* 3:533-539; Muzyczka, N. (1992) *Current Topics in Microbiol. and Immunol.* 158:97-20 129; and Kotin, R.M. (1994) *Human Gene Therapy* 5:793-801. Additional viral vectors which will find use for delivering the nucleic acid molecules encoding the antigens of interest include those derived from the pox family of viruses, including vaccinia virus and avian poxvirus.

If viral vectors are not wanted, liposomal preparations can alternatively be 25 used to deliver the nucleic acid molecules of the invention. Useful liposomal preparations include cationic (positively charged), anionic (negatively charged) and neutral preparations, with cationic liposomes particularly preferred. Cationic liposomes have been shown to mediate intracellular delivery of plasmid DNA (Felgner et al. (1987) *Proc. Natl. Acad. Sci. USA* 84:7413-7416) and mRNA (Malone 30 et al. (1989) *Proc. Natl. Acad. Sci. USA* 86:6077-6081).

As yet another alternative to viral vector systems, the nucleic acid molecules of the present invention may be encapsulated, adsorbed to, or associated with,

-17-

particulate carriers. Suitable particulate carriers include those derived from polymethyl methacrylate polymers, as well as PLG microparticles derived from poly(lactides) and poly(lactide-co-glycolides). See, e.g., Jeffery et al. (1993) *Pharm. Res.* 10:362-368. Other particulate systems and polymers can also be used, for 5 example, polymers such as polylysine, polyarginine, polyornithine, spermine, spermidine, as well as conjugates of these molecules.

Formulation of a composition comprising the above nucleic acid molecules can be carried out using standard pharmaceutical formulation chemistries and methodologies all of which are readily available to the reasonably skilled artisan.

10 For example, compositions containing one or more nucleic acid molecules can be combined with one or more pharmaceutically acceptable excipients or vehicles. Auxiliary substances, such as wetting or emulsifying agents, pH buffering substances and the like, may be present in the excipient or vehicle. These excipients, vehicles and auxiliary substances are generally pharmaceutical agents that do not induce an 15 immune response in the individual receiving the composition, and which may be administered without undue toxicity. Pharmaceutically acceptable excipients include, but are not limited to, liquids such as water, saline, polyethyleneglycol, hyaluronic acid, glycerol and ethanol. Pharmaceutically acceptable salts can also be included therein, for example, mineral acid salts such as hydrochlorides,

20 hydrobromides, phosphates, sulfates, and the like; and the salts of organic acids such as acetates, propionates, malonates, benzoates, and the like. Certain facilitators of nucleic acid uptake and/or expression can also be included in the compositions, for example, facilitators such as bupivacaine, cardiotoxin and sucrose. A thorough discussion of pharmaceutically acceptable excipients, vehicles and auxiliary 25 substances is available in REMINGTON'S PHARMACEUTICAL SCIENCES (Mack Pub. Co., N.J. 1991), incorporated herein by reference.

When used in nucleic acid immunizations, the formulated compositions will include an amount of the antigen of interest which is sufficient to mount an immunological response, as defined above. An appropriate effective amount can be 30 readily determined by one of skill in the art. Such an amount will fall in a relatively broad range that can be determined through routine trials. The compositions may contain from about 0.1% to about 99.9% of the antigen and can be administered

-18-

directly to the subject or, alternatively, delivered *ex vivo*, to cells derived from the subject, using methods known to those skilled in the art. For example, methods for the *ex vivo* delivery and reimplantation of transformed cells into a subject are known (e.g., dextran-mediated transfection, calcium phosphate precipitation,

5 electroporation, and direct microinjection into nuclei). Methods for *in vivo* delivery can entail injection using a conventional syringe. The constructs can be injected either subcutaneously, epidermally, intradermally, intramucosally such as nasally, rectally and vaginally, intraperitoneally, intravenously, orally or intramuscularly.

Other modes of administration include oral and pulmonary administration,

10 suppositories, and transdermal applications.

It is preferred, however, that the nucleic acid molecules be delivered using a particle acceleration device which fires nucleic acid-coated microparticles into target tissue, or transdermally delivers particulate nucleic acid compositions. In this regard, particle-mediated (sometimes referred to as "gene gun") nucleic acid immunization

15 has been shown to elicit both humoral and cytotoxic T lymphocyte immune responses following epidermal delivery of nanogram quantities of DNA. Pertmer et al. (1995) *Vaccine* 13:1427-1430. Particle-mediated delivery techniques have been compared to other types of nucleic acid inoculation, and found markedly superior.

Fynan et al. (1995) *Int. J. Immunopharmacology* 17:79-83, Fynan et al. (1993) *Proc.*

20 *Natl. Acad. Sci. USA* 90:11478-11482, and Raz et al. (1994) *Proc. Natl. Acad. Sci. USA* 91:9519-9523. Such studies have investigated particle-mediated delivery of nucleic acid-based vaccines to both superficial skin and muscle tissue.

Particle-mediated methods for delivering nucleic acid preparations are known in the art. Thus, once prepared and suitably purified, the above-described nucleic

25 acid molecules can be coated onto carrier particles using a variety of techniques known in the art. Carrier particles are selected from materials which have a suitable density in the range of particle sizes typically used for intracellular delivery from a gene gun device. The optimum carrier particle size will, of course, depend on the diameter of the target cells.

30 For the purposes of the invention, tungsten, gold, platinum and iridium carrier particles can be used. Tungsten and gold particles are preferred. Tungsten particles are readily available in average sizes of 0.5 to 2.0 μm in diameter. Gold particles or

-19-

microcrystalline gold (e.g., gold powder A1570, available from Engelhard Corp., East Newark, NJ) will also find use with the present invention. Gold particles provide uniformity in size (available from Alpha Chemicals in particle sizes of 1-3 μm , or available from Degussa, South Plainfield, NJ in a range of particle sizes 5 including 0.95 μm). Microcrystalline gold provides a diverse particle size distribution, typically in the range of 0.5-5 μm . However, the irregular surface area of microcrystalline gold provides for highly efficient coating with nucleic acids.

A number of methods are known and have been described for coating or precipitating DNA or RNA onto gold or tungsten particles. Most such methods 10 generally combine a predetermined amount of gold or tungsten with plasmid DNA, CaCl₂ and spermidine. The resulting solution is vortexed continually during the coating procedure to ensure uniformity of the reaction mixture. After precipitation of the nucleic acid, the coated particles can be transferred to suitable membranes and allowed to dry prior to use, coated onto surfaces of a sample module or cassette, or 15 loaded into a delivery cassette for use in particular gene gun instruments.

Various particle acceleration devices suitable for particle-mediated delivery are known in the art, and are all suited for use in the practice of the invention. Current device designs employ an explosive, electric or gaseous discharge to propel the coated carrier particles toward target cells. The coated carrier particles can 20 themselves be releasably attached to a movable carrier sheet, or removably attached to a surface along which a gas stream passes, lifting the particles from the surface and accelerating them toward the target. An example of a gaseous discharge device is described in U.S. Patent No. 5,204,253. An explosive-type device is described in U.S. Patent No. 4,945,050. One example of a helium discharge-type particle 25 acceleration apparatus is the PowderJect XR® instrument (PowderJect Vaccines, Inc., Madison), WI, which instrument is described in U.S. Patent No. 5,120,657. An electric discharge apparatus suitable for use herein is described in U.S. Patent No. 5,149,655. The disclosure of all of these patents is incorporated herein by reference.

The particulate nucleic acid compositions can alternatively be administered 30 transdermally using a needleless syringe device. For example, a particulate composition comprising the nucleic acid constructs of the present invention can be obtained using general pharmaceutical methods such as simple evaporation

-20-

(crystallization), vacuum drying, spray drying or lyophilization. If desired, the particles can be further densified using the techniques described in commonly owned International Publication No. WO 97/48485, incorporated herein by reference. These particulate compositions can then be delivered from a needleless syringe system such

5 as those described in commonly owned International Publication Nos. WO 94/24263, WO 96/04947, WO 96/12513, and WO 96/20022, all of which are incorporated herein by reference.

The particle compositions or coated particles are administered to the individual in a manner compatible with the dosage formulation, and in an amount

10 that will be effective for the purposes of the invention. The amount of the composition to be delivered depends on the individual to be tested. The exact amount necessary will vary depending on the age and general condition of the individual to be treated, and an appropriate effective amount can be readily determined by one of skill in the art upon reading the instant specification.

15

C. Experimental

Below are examples of specific embodiments for carrying out the present invention. The examples are offered for illustrative purposes only, and are not intended to limit the scope of the present invention in any way.

20 Efforts have been made to ensure accuracy with respect to numbers used (e.g., amounts, temperatures, etc.), but some experimental error and deviation should, of course, be allowed for.

Example 1

25

A number of expression systems were constructed to compare antigen expression from vectors containing an antigen coding sequence under transcriptional control of an enhanced promoter and the corresponding minimal promoter (using *in vitro* expression testing methods). The immunogenicity of the same vector constructs was then assessed (ability to elicit an antibody response against the antigen) using *in vivo* nucleic acid immunization testing methods.

Particularly, vectors containing the simian CMV promoter with ("sCMV")

-21-

and without ("mP-sCMV") its enhancer, vectors containing the human CMV immediate early promoter with ("CMV") and without ("mp" or "mP-CMV") its enhancer, and vectors containing the PRV promoter with ("PRV") and without ("mP-PRV") its enhancer were assessed for both antigen production (*in vitro* expression) 5 and for antibody production (*in vivo* immunogenicity). The results are depicted in the attached figure. In all cases, removal of the enhancer sequences reduced expression levels from the minimal promoter constructs (relative to the enhanced promoters) (not shown). However, as can be seen in the figure, the minimal promoter constructs provided for dramatically increased antibody production 10 (relative to the enhanced promoters) in the *in vivo* component of the study

Example 2

In order to further assess the effect of using an enhancer-less promoter system 15 in a nucleic acid immunization protocol, a number of experiments were carried out to compare the immunogenicity of antigen constructs containing full-length (enhanced) promoter systems and the minimal (enhancer-less) promoter systems of the present invention.

More particularly, a series of Hepatitis B surface antigen (HBsAg) constructs 20 were constructed as follows. To generate the HBsAg coding region, the pAM6 construct (obtained from the American Type Culture Collection "ATCC") was cut with *Nco*1 and treated with mung bean nuclease to remove the start codon of the X- antigen. The resultant DNA was then cut with *Bam*H1 and treated with T4 DNA polymerase to blunt-end the DNA and create an HBsAg expression cassette. The 25 HBsAg expression cassette is present in the 1.2 kB fragment. The plasmid construct PJV7077 (Schmaljohn et al. (1997) *J. Virol.* 71:9563-9569) which contains the full-length human CMV (Towne strain) immediate early promoter (with enhancer) was cut with *Hind*3 and *Bgl*2, and then treated with T4 DNA polymerase and calf-alkaline phosphatase to create blunt-ended DNA adjacent.

30 The PJV7232 host plasmid (a derivative of the PJV7077 construct described above) contains a promoter insertion region flanked by a *Sall* and *Bam*H1 site. New promoters were PCRer out of viral stocks, infected cells, plasmids, etc., using

-22-

primers homologous to the promoter region of interest. These primers were designed with *SalI* and *BamH1* restriction sites at the terminal ends such that the PCR fragment can be cut with these enzymes to facilitate ready insertion into the similarly cut PJV7232 construct. This method was then used to construct HBsAg expression 5 cassettes driven by full-length (enhanced) simian CMV (sCMV) and pseudorabies virus (PRV) promoter systems. All PCR reactions were carried out under standard conditions to amplify the promoter elements from the target sequences according to manufacturer instructions, particularly:

10 1x PCR core buffer w/ 15mM MgCl₂;

10 0.4 μM each of sense and antisense primers;

10 200 μM of each dNTP;

10 2.5 μg Taq polymerase;

10 0.1-1.0 μg target sample (ATCC# VR706 for sCMV and ATCC# VR135 for PRV);

15 water to 100 μL; and

15 mineral oil overlay.

the thermocycler was programmed to run the following routine:

20 4 minutes at 95°C;

20 30 cycles of (1 minute at 95° + 1 min.15 sec. at 55°C + 1 min. at 72°C);

20 10 minutes at 72°C; and

20 4°C hold.

After thermocycling was completed, the Taq polymerase was removed by 25 phenol/chloroform extraction and ethanol precipitation of the PCR products. This amplified DNA, as well as the PJV7232 construct were then cut with the *SalI* and *BamH1* restriction enzymes.

After being cut with the appropriate restriction enzymes (and blunt-ended if needed), the DNAs were run on an agarose gel to separate, purify and isolate DNA 30 bands of interest. These isolated bands were then mixed together in a ligase reaction and incubated overnight at 16°C. The ligation reactions were transformed into *E.coli* cells. The cut PJV7077 or PJV7232 constructs are not able to grow in the bacterial

-23-

host cells under antibiotic selection unless they contain an appropriate insert fragment. Accordingly, bacterial colonies containing the new recombinant DNA constructs (the HbsAG sequence promoted by a full length hCMV, sCMV or PRV promoter) were grown on an agar plate, and the DNA was isolated from these

5 colonies. The DNA was analysed for proper ligation of the various fragments. Bacterial isolates which harbor correct ligation products were amplified in a large liquid culture, on which a large-scale DNA extraction was performed. The resultant DNA is then used as a vaccine lot

In order to make corresponding minimal promoter (enhancer-less) versions of

10 the above-described hCMV-sAG, sCMV-sAG and PRV-sAG constructs, the DNAs were cut with restriction enzyme pairs (*Sal*1/*Bam*1, *Sal*1/*Sca*1, or *Sal*1/*Not*1, respectively). The cut DNA was treated with T4 DNA polymerase to create blunt-ended DNA. The blunt-ended DNA was self-ligated, transformed, analyzed and amplified using the same conditions set forth herein above. This procedure produced

15 vaccine lots were at least the majority of each enhancer sequence was deleted from the promoter.

The DNA vaccine products were then coated onto gold carrier particles and administered to murine subjects using a particle-mediated delivery technique. Specifically, for each plasmid DNA construct to be tested, 25 mg of 2 µm gold

20 powder was weighed into a microfuge tube. After addition of a 250 µL aliquot of 50 mM spermidine (Aldrich), the tubes were vortexed and briefly sonicated. The gold was then microfuged out, and the spermidine replaced by a fresh 100 µL aliquot. The gold was then resuspended by vortexing, after which 25 µg of DNA was added to the tubes and mixed. While the tube is lightly vortexed, 100 µL of 10% CaCl

25 (Fujisawa) USA, Inc.) was added to precipitate the DNA onto the gold beads. The precipitation reaction was allowed to proceed for ten minutes on the benchtop, after which the gold was collected by a brief microfuge spin and washed three times with absolute ethanol (Spectrum) to remove excess precipitation reagents. The washed gold/DNA complex was then resuspended with 0.05 mg/mL polyvinylpyrrolidone

30 (360 kD, Spectrum) in absolute ethanol. The resultant slurry was then injected into a TEFZEL® tube (McMaster-Carr) housed in a tube turner coating machine (PowderJect Vaccines, Inc., Madison WI) which coats the inside of the tube with the

-24-

gold/DNA complex. This tube turner machine is described in US Patent No. 5,733,600. After the coating procedure was completed, the tubes were cut into 0.5 inch "shots" which were loaded into a particle-mediated delivery device (the PowderJect XR1 device, PowderJect Vaccines, Inc., Madison, WI) for delivery into 5 the mice.

For the vaccination procedures, four- to six-week old Balb/c mice were anesthetized with a mixture of KETASET® (Fort Dodge) and ROMPUN® (Bayer) anesthetics. The bellies were shaved with a pair of electric clippers to remove hair, and two non-overlapping "shots" of vaccine were delivered from the PowderJect 10 XR1 device (at 450 psi) to the shaved area. The animals were returned to their cages for six weeks after which time blood samples were obtained for sera analysis of anti-HBsAg antibodies.

More particularly, blood samples were harvested from the vaccinated animals. Up to 200 µL aliquots of serum isolated from the blood samples were then 15 placed int wells of a reaction vessel supplied with the AUSAB® EIA Diagnostic Kit (Abbott Laboratories). The amount of sera added depended upon the antibody titer of the sample, and each sample was diluted with sample dilution buffer to fall within values that are readable by the immunoassay kit. 200 µL aliquots of standardization panel samples were added to the wells of the reaction vessel. A bead was added to 20 each well, after which the vessel was sealed and incubated for two hours at 40°C. The wells were then washed of all liquid reaction components. 200 µL aliquots of the conjugate mix was then added to each washed well, after which the vessel was sealed and incubated for two hours again at 40°C. The wells were then washed of all liquid reaction components, and the bead transferred to new reaction tubes after 25 which 300 µL of the color development buffer was added. After 30 minutes, the color development reaction was stopped by addition of 1M H₂SO₄, and the absorbance was measured at 490nm using a Quantum II™ spectrophotometer. The spectrophotometer was used to calculate antibody levels of each sample by comparison of the absorbance of the sample against a standard curve generated with 30 a standardization panel. The antibody levels were then corrected for any dilution factors, and the final data reported as the geometric mean titers of all animals vaccinated with a particular DNA vaccine construct.

-25-

The results of these studies are depicted in Figures 2-4. Figure 2 shows a comparison between the fully enhanced hCMV promoter system and the minimal hCMV promoter system of the present invention. As can be seen, the minimal promoter system gave an approximately three-fold improvement in antibody titer
5 over the fully enhanced promoter system (the results were pooled from four independent experiments of 8 mice per group). Figures 3 and 4 show similar results from comparisons between full-length (enhanced) promoters and their corresponding minimal (enhancer-less) promoter derivatives.

Accordingly, novel minimal promoter systems and nucleic acid reagents
10 comprising these systems have been described. Although preferred embodiments of the subject invention have been described in some detail, it is understood that obvious variations can be made without departing from the spirit and the scope of the invention as defined by the appended claims.

-26-

CLAIMS

1. Use of a nucleic acid construct comprising a minimal promoter sequence operably linked to a coding sequence encoding a polypeptide of interest in the manufacture of a medicament for use in obtaining expression in mammalian cells of the said polypeptide.
2. Use according to claim 1, wherein the coding sequence encodes an antigen and the medicament is for use in nucleic acid immunization.
3. Use according to claim 2, wherein the antigen is an antigen of a viral, bacterial, parasite or fungal pathogen.
- 10 4. Use according to claim 2, wherein the antigen is a tumor-specific antigen or an antigen associated with an autoimmune disease.
5. Use according to any one of claims 2 to 4, wherein the antigen comprises a B-cell epitope or a T-cell epitope.
- 15 6. Use according to any one of claims 2 to 5, wherein the nucleic acid construct is coated onto carrier particles.
7. Use according to claim 1, wherein the medicament is for use in gene therapy.
8. Use according to claim 7, wherein the nucleic acid construct is provided in a viral vector or liposomal preparation.
- 20 9. Use according to any one of the preceding claims, wherein the nucleic acid construct is DNA construct.
10. Use according to any one of the preceding claims, wherein the minimal promoter sequence consists essentially of a human cytomegalovirus (hCMV) immediate early promoter sequence, a pseudorabies virus (PRV) early promoter region, a simian cytomegalovirus (sCMV) immediate early promoter sequence or a functional variant thereof.
- 25 11. Use according to claim 10, wherein the minimal promoter sequence consists essentially of the sequence spanning positions 0 to -118 of the hCMV immediate early promoter region or a functional variant of the said spanning sequence.
- 30 12. A method of obtaining expression in mammalian cells of a polypeptide of interest, which method comprises transferring into said cells a nucleic

-27-

acid construct comprising a minimal promoter sequence operably linked to a coding sequence for the said polypeptide.

13. A method according to claim 12, wherein the construct is delivered directly into a subject.

5 14. A method according to claim 13, wherein the construct is delivered by injection, transdermal particle delivery, inhalation, topically, orally, intranasally or transmucosally.

15. A method according to claim 14, wherein the construct is delivered by needleless injection.

10 16. A method according to claim 12, wherein the construct is delivered *ex vivo* into cells taken from a subject and the cells are reintroduced into the subject.

17. A method according to any one of claims 13 to 16, wherein the subject is a human.

15 18. A method according to any one of claims 12 to 17, wherein the polypeptide is an antigen.

19. A method according to claim 18, wherein the antigen is an antigen of a viral, bacterial, parasite or fungal pathogen.

20. A method according to claim 18, wherein the antigen is a tumor-specific antigen or an antigen associated with an autoimmune disease.

20 21. A method according to any one of claims 18 to 20, wherein the antigen comprises a B-cell epitope or a T-cell epitope.

22. A method according to any one of claims 12 to 21, wherein the nucleic acid construct is coated onto carrier particles.

25 23. A method according to any one of claims 12 to 22, wherein the nucleic acid construct is a DNA construct.

24. A method according to any one of the preceding claims, wherein the minimal promoter sequence consists essentially of a human cytomegalovirus (hCMV) immediate early promoter sequence, a pseudorabies virus (PRV) early promoter region, a simian cytomegalovirus (sCMV) immediate early promoter sequence or a functional variant thereof.

30 25. A method according to claim 24, wherein the minimal promoter sequence consists essentially of the sequence spanning positions 0 to -118 of the

-28-

hCMV immediate early promoter region or a functional variant of the said spanning sequence.

26. Coated particles suitable for use in particle-mediated nucleic acid immunisation, which particles comprise carrier particles coated with a nucleic acid construct comprising a minimal promoter sequence operably linked to a coding sequence encoding an antigen.
 - 5 27. Coated particles according to claim 26, wherein the carrier particles are tungsten or gold particles.
 - 10 28. Coated particles according to claim 26 or 27, wherein the antigen is an antigen of a viral, bacterial, parasite or fungal pathogen..
 - 15 29. Coated particles according to claim 26 or 27, wherein the antigen is a tumor-specific antigen or an antigen associated with an autoimmune disease.
 30. Coated particles according to any one of claims 26 to 29, wherein the antigen comprises a B-cell epitope or a T-cell epitope.
 - 15 31. Coated particles according to any one of claims 26 to 30, wherein the nucleic acid construct is DNA construct.
 32. Coated particles according to any one of claims 26 to 31, wherein the minimal promoter sequence consists essentially of a human cytomegalovirus (hCMV) immediate early promoter sequence, a pseudorabies virus (PRV) early promoter region, a simian cytomegalovirus (sCMV) immediate early promoter sequence or a functional variant thereof.
 - 20 33. Coated particles according to claim 32, wherein the minimal promoter sequence consists essentially of the sequence spanning positions 0 to -118 of the hCMV immediate early promoter region or a functional variant of the said spanning sequence.
 - 25 34. A particle acceleration device suitable for particle-mediated nucleic acid immunisation, the said device being loaded with coated particles as defined in any one of claims 26 to 33.
 35. A purified, isolated minimal promoter sequence.
 - 30 36. A nucleic acid construct comprising a minimal promoter sequence operably linked to a coding sequence.
 37. A vector comprising the nucleic acid construct of claim 36.

-29-

38. A vector according to claim 37 which is a plasmid.

(54) Title: MINIMAL PROMOTERS AND USES THEREOF

GMT of Anti-HBsAg Antibodies (mIU/ml) At Six Weeks Post-Prime (Four Experiments @ 8 Mice per Group)

(57) Abstract

Minimal promoter sequences are described. Reagents including a nucleic acid molecule which contains these minimal promoter sequences are also described. Methods for constructing these reagents, and methods for using these reagents are also described.

INTERNATIONAL SEARCH REPORT

Inte ~~onal~~ Application No

PCT/US 99/24694

A. CLASSIFICATION OF SUBJECT MATTER
 IPC 7 C12N15/12 A61K48/00 C12M1/00

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)
 IPC 7 A61K

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X	<p>WO 98 20041 A (OKLAHOMA MED RES FOUND) 14 May 1998 (1998-05-14)</p> <p>page 2, line 7 -page 3, line 11 page 7 -page 8; example 1 figure 4 page 5, line 13 -page 6, line 28 page 7, line 4 - line 21; claims 1-3</p> <hr/> <p style="text-align: center;">-/-</p>	<p>1,7-9, 12-17, 22,23, 35-37</p>

Further documents are listed in the continuation of box C.

Patent family members are listed in annex.

* Special categories of cited documents :

- "A" document defining the general state of the art which is not considered to be of particular relevance
- "E" earlier document but published on or after the international filing date
- "L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- "O" document referring to an oral disclosure, use, exhibition or other means
- "P" document published prior to the international filing date but later than the priority date claimed

- "T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
- "X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
- "Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.
- "&" document member of the same patent family

INTERNATIONAL SEARCH REPORT

International application No.

PCT/US 99/24694

Box I Observations where certain claims were found unsearchable (Continuation of Item 1 of first sheet)

This International Search Report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. Claims Nos.:

because they relate to subject matter not required to be searched by this Authority, namely:

Remark: Although claims 13-17 completely, and 12, 18-25 partially, are directed to a method of treatment of the human/animal body, the search has been carried out and based on the alleged effects of the compound/composition.

2. Claims Nos.:

because they relate to parts of the International Application that do not comply with the prescribed requirements to such an extent that no meaningful International Search can be carried out, specifically:

3. Claims Nos.:

because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II Observations where unity of invention is lacking (Continuation of Item 2 of first sheet)

This International Searching Authority found multiple inventions in this International application, as follows:

1. As all required additional search fees were timely paid by the applicant, this International Search Report covers all searchable claims.

2. As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.

3. As only some of the required additional search fees were timely paid by the applicant, this International Search Report covers only those claims for which fees were paid, specifically claims Nos.:

4. No required additional search fees were timely paid by the applicant. Consequently, this International Search Report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest

The additional search fees were accompanied by the applicant's protest.

No protest accompanied the payment of additional search fees.

AMENDED CLAIMS

[received by the International Bureau on 16 June 2000 (16.06.00);
original claims 1-38 replaced by new claims 1-40 (5 pages)]

1. A method for making a food product comprising comminuting a precooked starchy food selected from the group consisting of potato, corn, rice, wheat, beans, and mixtures thereof to fine starchy particles, wherein at least about 90% by weight of said fine starchy food particles have a particle size of less than about 10 microns.
2. The method of Claim 42 in which at least about 90% by weight of said fine starchy food particles have a particle size of less than about 25 microns.
10
3. The method of Claim 42 wherein at least about 90% by weight of said fine starchy food particles have a particle size of less than about 10 microns.
4. The method of Claim 1 wherein said precooked starchy food is comminuted to form a slurry of starchy food particles in an aqueous liquid and said slurry is homogenized to form said fine starchy food particles.
15
5. The method of Claim 4 wherein said precooked starchy food particles are dried prior to homogenization, and wherein said slurry is held at an elevated temperature for sufficient time to swell the starchy food.
20
6. The method of Claim 5 in which said elevated temperature is in excess of about 110°F.
25
7. The method of Claim 5 in which said slurry is held for at least 10 minutes prior to homogenization.
8. The method of Claim 4 in which the weight ratio of aqueous liquid to starchy food particles in said dispersion is from about 3:1 to about 10:1.
30
9. The method of Claim 5 in which the slurry forms a substantially continuous

flowable mass prior to homogenization.

10. The method of Claim 5 in which most of said aqueous liquid is absorbed by said precooked starchy food particles prior to homogenization.

5

11. The method of Claim 4 in which said homogenization is performed at a pressure in excess of about 3,000 psig.

12. The method of Claim 4 further comprising drying the homogenized slurry to
10 form a starchy food powder.

13. The method of Claim 12 wherein said drying is performed by spray drying.

14. The method of Claims 1 or 42 in which said starchy food comprises potato
15 granules.

15. The method of Claims 1 or 42 in which said starchy food comprises potato flakes.

16. The method of Claims 1 or 42 in which said starchy food comprises fresh
20 precooked potato.

17. A fat substitute prepared by the method of Claims 1 or 42.

18. A food product comprising precooked fine starchy food particles, said starchy food
25 being selected from the group consisting of potato, corn, rice, wheat, beans, and
mixtures thereof, wherein at least about 90% by weight of said fine particles have a
particle size less than about 10 microns.

19. The food product of Claim 19 further comprising an aqueous solution in which said
30 fine starchy food particles are dispersed thereby forming a slurry.

20. The food product of Claims 19 or 43 in the form of a fat substitute in a mixture with additional ingredients to form a member selected from the group consisting of batter breading, a beverage, a bakery product, sauces, cultured dairy products, confections, puddings, ice cream, butter, margarine, salad dressing, mayonnaise, cheese products, frozen confections, fruit preparations, fluid milk products and substitutes, snack food products, soup, sauces, dips, and structured meat products.

5

21. The mixture of Claim 22 wherein said fine particles comprise at least about 0.1% on a dry weight basis of said mixture.

10

22. A food product comprising precooked starchy food fine particles, characterized in that a 5% dispersion of said starchy food fine particles at 30°C have a higher viscosity than that of a 5% dispersion of said starchy food fine particles at 70°C.

15

23. The food product of Claim 24 wherein said viscosity at 30°C has a higher viscosity has at least about 10% greater than said viscosity at 70°C.

24. The food product of Claim 24 wherein said viscosity at 30°C is about 20 cp or greater.

20

25. The food product of Claim 24 wherein said viscosity at 30°C is about 22 cp or greater.

26. The food product of Claim 24 wherein said starchy food fine particles have a hydrophile-lipophile balance value of about 16 or greater.

25

27. The food product of Claim 19 characterized in that the starchy food fine particles comprises a powder comprising aggregates of said fine particles wherein at least about 50% by weight of said aggregates have a size between about 20 microns to about 70

30

microns.

28. The food product of Claim 24 in the form of a fat substitute in a mixture with additional ingredients to form a food composition selected from the group consisting of batter breading, a beverage, a bakery product, sauces, cultured dairy products, confections, puddings, ice cream, butter, margarine, salad dressing, mayonnaise, cheese products, frozen confections, fruit preparations, fluid milk products and substitutes, snack food products, soup, sauces, dips, and structured meat products.

10 29. The mixture of Claim 30 wherein said fine particles comprise at least about 0.1% on a dry weight basis of said food product.

15 30. The food product of Claim 19 in which said starchy food comprises potato granules.

31. The food product of Claim 19 in which said starchy food comprises potato flakes.

15 32. The food product of Claim 19 in which said starchy food comprises fresh precooked potatoes.

20 33. The method of Claim 1 in which said food product is suitable for use as a fat substitute.

34. The food product of Claims 19 or 24 suitable for use as a fat substitute.

25 35. A method for making a food product comprising comminuting precooked starchy food selected from the group consisting of potato, beans, and mixtures thereof, comprising dispersing said starchy food in particle form in an aqueous liquid to form a slurry and homogenizing said slurry to form fine starchy food particles.

30 36. The method of Claim 38 in which said fine starchy food particles are suitable for use as a fat substitute.

37. The method of Claim 38 in which said homogenizing is performed at a pressure of at least about 1000 psi.

38. The method of Claim 38 in which said homogenizing is performed at a pressure of at least about 3000 psi.

39. A method for making a food product comprising comminuting a precooked starchy food selected from the group consisting of potato, beans and mixtures thereof to fine starchy food particles, wherein at least about 90% by weight of said fine starchy food particles have a particle size of less than about 50 microns.

40. A food product suitable for use as a fat substitute comprising precooked starchy fine food particles selected from the group consisting of potato, beans and mixtures thereof, wherein at least about 90% by weight of said fine particles have a particle size less than about 50 microns.

(54) Title: MINIMAL PROMOTERS AND USES THEREOF

(57) Abstract

Minimal promoter sequences are described. Reagents including a nucleic acid molecule which contains these minimal promoter sequences are also described. Methods for constructing these reagents, and methods for using these reagents are also described.

MINIMAL PROMOTERS AND USES THEREOF

Technical Field

The invention relates to the general fields of molecular biology and immunology, and generally relates to reagents useful in nucleic acid immunization techniques. More specifically, the invention relates to truncated forms of transcriptional promoter elements, nucleic acid molecules containing such promoter elements, and to the use of reagents containing such nucleic acid molecules for nucleic acid immunization and gene therapy.

10

Background

Techniques for the injection of DNA and mRNA into mammalian tissue for the purposes of immunization against an expression product have been described in the art. See, e.g., European Patent Specification EP 0 500 799 and U.S. Patent No. 5,589,466. The techniques, termed "nucleic acid immunization" herein, have been shown to elicit both humoral and cell-mediated immune responses. For example, sera from mice immunized with a DNA construct encoding the envelope glycoprotein, gp160, were shown to react with recombinant gp160 in immunoassays, and lymphocytes from the injected mice were shown to proliferate in response to recombinant gp120. Wang et al. (1993) *Proc. Natl. Acad. Sci. USA* 90:4156-4160. Similarly, mice immunized with a human growth hormone (hGH) gene demonstrated an antibody-based immune response. Tang et al. (1992) *Nature* 356:152-154. Intramuscular injection of DNA encoding influenza nucleoprotein driven by a mammalian promoter has been shown to elicit a CD8+ CTL response that can protect mice against subsequent lethal challenge with virus. Ulmer et al. (1993) *Science* 259:1745-1749. Immunohistochemical studies of the injection site revealed that the DNA was taken up by myeloblasts, and cytoplasmic production of viral protein could be demonstrated for at least 6 months.

It has been a major aim of artisans practising in the fields of gene therapy and nucleic acid immunization to identify and design expression systems that provide as high a level of production as possible for a gene or sequence of interest that has been delivered into a host cell. High level production is seen as being a necessary

-2-

prerequisite for any expression system used in gene therapy (to provide for sufficient levels of a therapeutic gene product) or nucleic acid immunization (to provide for a sufficient immune response against an encoded antigen product). Several factors are known to affect the level of production attainable from such transfected host cells,

5 including transfection efficiency (e.g., the copy number in the cell) and the efficiency with which the gene or sequence of interest is transcribed and the mRNA translated.

Accordingly, a number of expression systems have been described in the art, each of which typically consists of a vector containing a gene or nucleotide sequence of interest operably linked to expression control sequences which control the

10 expression of the gene or nucleotide sequence. These control sequences include transcriptional promoter sequences and transcriptional start and termination sequences. Transcriptional promoter sequences are generally located just upstream of initiation sites for RNA transcripts, and include a "TATA" box and a "CAAT" box, respectively located about 30 and 80 nucleotides upstream (e.g., at about the -30

15 and -80 position) relative to the initiation site. Corden et al. (1980) *Science* 209:1406-1414; Chambon, P. (1981) *Ann. Rev. Biochem.* 50:349-383. Commonly used promoters for mammalian cell expression systems include the SV40 early promoter, a CMV promoter such as the CMV immediate early promoter (Chapman et al. (1991) *Nucl. Acids Res.* 19:3979-3986), the mouse mammary tumor virus LTR

20 promoter, the adenovirus major late promoter (Ad MLP), and the herpes simplex virus promoter, among others. Nonviral promoters, such as a promoter derived from the murine metallothionein gene, are also commonly used for such expression systems. These promoter systems are normally selected to provide for the highest level of expression possible for a given sequence.

25 A number of transcriptional modulator elements that are found more than 110 nucleotides upstream (-110) of various genes have also been commonly used in the art. These upstream sequences are deemed essential for the expression of early genes in simian, murine and human DNA viruses, and are commonly referred to as "enhancers." Enhancers are broadly defined as a cis-acting agent which, when

30 operably linked to a promoter/gene sequence, will dramatically increase transcription of that gene sequence. Enhancers can function from positions that are much further away from a sequence of interest than other expression control elements (e.g.,

-3-

promoters), and can operate when positioned in either orientation relative to the sequence of interest. Banerji et al. (1981) *Cell* 27:299-308, deVilleirs et al. (1981) *Nucleic Acids Research* 9:6251-6264. Enhancers have been identified from a number of viral sources, including polyoma virus, BK virus, cytomegalovirus 5 (CMV), adenovirus, simian virus 40 (SV40), Moloney sarcoma virus, bovine papilloma virus, and Rous sarcoma virus (deVilleirs et al. *supra*, Rosenthal et al. (1983) *Science* 222:749-755, Hearing et al. (1983) *Cell* 33:695-703, Weeks et al. (1983) *Mol. Cell. Biol.* 3:1222-1234, Levinson et al. (1982) *Nature* 295:568-572, and Luciw et al. (1983) *Cell* 33:705-716. These enhancer elements are often coupled 10 with homologous and heterologous promoter sequences to provide enhancer/promoter pairs for use in expression systems. However, probably the most frequently used enhancer/promoter pair used in gene therapy and nucleic acid immunization is the hCMV immediate-early enhancer/promoter pair. See e.g., U.S. Patent Nos. 5,168,062 and 5,385,839 to Stinski, and EP Patent Specification 0 323 15 997 B1. The hCMV enhancer element has also been used without the hCMV promoter element, for example to modulate a heterologous promoter sequence. See e.g., EP Patent Specification 0 173 177 B1. The hCMV immediate-early enhancer/promoter pair provides for robust expression from a variety of different sequences of interest, and this high level expression is commonly thought of as 20 establishing the "gold standard" for any given expression system.

Summary of the Invention

It is a primary object of the invention to provide a promoter system which provides a better expression character in mammalian cells, particularly *in vivo*. It has 25 now surprisingly been found that the use of a promoter sequence that normally is paired with its homologous enhancer sequence in an expression system will provide for a greatly enhanced immune response against an encoded antigen when the promoter is used in a truncated, enhancer-less form in an expression system. The "enhancerless" promoter sequence is referred to herein as a "minimal promoter." An 30 improved immunological response to a nucleic acid vaccine composition which incorporates the promoter system can be achieved. More efficient gene therapy may also be achieved.

-4-

Accordingly, the present invention provides use of a nucleic acid construct comprising a minimal promoter sequence operably linked to a coding sequence encoding a polypeptide of interest in the manufacture of a medicament for use in obtaining expression in mammalian cells of the said polypeptide. The invention also 5 provides:

- a method of obtaining expression in mammalian cells of a polypeptide of interest, which method comprises transferring into said cells a nucleic acid construct comprising a minimal promoter sequence operably linked to a coding sequence for the said polypeptide;
- 10 - coated particles suitable for use in particle-mediated nucleic acid immunisation, which particles comprise carrier particles coated with a nucleic acid construct comprising a minimal promoter sequence operably linked to a coding sequence encoding an antigen;
- a particle acceleration device suitable for particle-mediated nucleic acid immunisation, the said device being loaded with coated particles of the invention;
- a purified, isolated minimal promoter sequence; and
- a nucleic acid construct comprising a minimal promoter sequence operably linked to a coding sequence

20 The nucleic acid construct may be present in a vector construct, for example in a plasmid vector or in a recombinant viral vector. A nucleic acid immunization reagent capable of eliciting an immune response against an antigen of interest is thus provided, the reagent comprising a nucleic acid construct which includes a nucleic acid sequence of interest under the transcriptional control of a minimal promoter

25 sequence. Expression systems can be constructed for use in nucleic acid immunization to provide for a greatly enhanced immune response against an antigen of interest.

These and other objects, aspects, embodiments and advantages of the present invention will readily occur to those of ordinary skill in the art in view of the 30 disclosure herein.

-5-

Brief Description of the Figures

Figure 1 depicts a comparison between the minimal promoter constructs of the present invention and their corresponding enhanced promoter constructs. The *in vivo* performance of the promoter constructs was assessed by measuring antibody 5 production against the antigen of interest in animals receiving nucleic acid immunization with the constructs.

Figure 2 depicts a comparison between a minimal human cytomegalovirus (hCMV) promoter construct produced according to the present invention, and its 10 corresponding, fully enhanced hCMV promoter construct.

Figures 3 and 4 also depict comparison results obtained from *in vivo* vaccination studies using the minimal promoter constructs of the present invention and their corresponding enhanced promoter constructs. Here again, the *in vivo* 15 performance of the promoter constructs was assessed by measuring antibody production against the antigen of interest in animals receiving nucleic acid immunization with the constructs.

Detailed Description of the Preferred Embodiments

Before describing the present invention in detail, it is to be understood that 20 this invention is not limited to particularly exemplified molecules or process parameters as such may, of course, vary. It is also to be understood that the terminology used herein is for the purpose of describing particular embodiments of the invention only, and is not intended to be limiting. In addition, the practice of the present invention will employ, unless otherwise indicated, conventional methods of 25 virology, microbiology, molecular biology, recombinant DNA techniques and immunology all of which are within the ordinary skill of the art. Such techniques are explained fully in the literature. See, e.g., Sambrook, et al., *Molecular Cloning: A Laboratory Manual* (2nd Edition, 1989); *DNA Cloning: A Practical Approach*, vol. I & II (D. Glover, ed.); *Oligonucleotide Synthesis* (N. Gait, ed., 1984); *A Practical Guide to Molecular Cloning* (1984); and *Fundamental Virology*, 2nd Edition, vol. I & II (B.N. Fields and D.M. Knipe, eds.).

-6-

All publications, patents and patent applications cited herein, whether *supra* or *infra*, are hereby incorporated by reference in their entirety.

It must be noted that, as used in this specification and the appended claims, the singular forms "a," "an" and "the" include plural referents unless the content
5 clearly dictates otherwise.

A. Definitions

Unless defined otherwise, all technical and scientific terms used herein have the same meaning as commonly understood by one of ordinary skill in the art to
10 which the invention pertains. Although a number of methods and materials similar or equivalent to those described herein can be used in the practice of the present invention, the preferred materials and methods are described herein.

In describing the present invention, the following terms will be employed, and are intended to be defined as indicated below.

15 The term "nucleic acid immunization" is used herein to refer to the introduction of a nucleic acid molecule encoding one or more selected antigens into a host cell for the *in vivo* expression of the antigen or antigens. The nucleic acid molecule can be introduced directly into the recipient subject, such as by injection; transdermal particle delivery; inhalation; topically, or by oral, intranasal or mucosal
20 modes of administration. The molecule alternatively can be introduced *ex vivo* into cells which have been removed from a subject. In this latter case, the cells are reintroduced into the subject where an immune response can be mounted against the antigen encoded by the nucleic acid molecule.

An "antigen" refers to any agent, generally a macromolecule, which can elicit
25 an immunological response in an individual. The term may be used to refer to an individual macromolecule or to a homogeneous or heterogeneous population of antigenic macromolecules. As used herein, "antigen" is generally used to refer to a protein molecule or portion thereof which comprises one or more epitopes. For purposes of the present invention, antigens can be obtained or derived from any
30 known virus, bacteria, parasite or fungal pathogen. The term also intends any of the various tumor-specific antigens and antigens associated with autoimmune diseases. Furthermore, for purposes of the present invention, an "antigen" includes a protein

having modifications, such as deletions, additions and substitutions (generally conservative in nature) to the native sequence, so long as the protein maintains sufficient immunogenicity. These modifications may be deliberate, for example through site-directed mutagenesis, or may be accidental, such as through mutations of hosts which produce the antigens.

In various aspects of the invention, the antigen contains one or more T cell epitopes. A "T cell epitope" refers generally to those features of a peptide structure which are capable of inducing a T cell response. In this regard, it is accepted in the art that T cell epitopes comprise linear peptide determinants that assume extended conformations within the peptide-binding cleft of MHC molecules, (Unanue et al. 10 (1987) *Science* 236:551-557). As used herein, a T cell epitope is generally a peptide having at least about 3-5 amino acid residues, and preferably at least 5-10 or more amino acid residues. The ability of a particular antigen to stimulate a cell-mediated immunological response may be determined by a number of well-known assays, such 15 as by lymphoproliferation (lymphocyte activation) assays, CTL cytotoxic cell assays, or by assaying for T-lymphocytes specific for the antigen in a sensitized subject. See, e.g., Erickson et al. (1993) *J. Immunol.* 151:4189-4199; and Doe et al. (1994) *Eur. J. Immunol.* 24:2369-2376.

In other aspects of the invention, the antigen contains one or more B cell epitopes. A "B cell epitope" generally refers to the site on an antigen to which a specific antibody molecule binds. The identification of epitopes which are able to elicit an antibody response is readily accomplished using techniques well known in the art. See, e.g., Geysen et al. (1984) *Proc. Natl. Acad. Sci. USA* 81:3998-4002 (general method of rapidly synthesizing peptides to determine the location of 20 immunogenic epitopes in a given antigen); U.S. Patent No. 4,708,871 (procedures for identifying and chemically synthesizing epitopes of antigens); and Geysen et al. (1986) *Molecular Immunology* 23:709-715 (technique for identifying peptides with 25 high affinity for a given antibody).

An "immune response" against an antigen of interest is the development in an 30 individual of a humoral and/or a cellular immune response to that antigen. For purposes of the present invention, a "humoral immune response" refers to an immune response mediated by antibody molecules, while a "cellular immune response" is one

-8-

mediated by T-lymphocytes and/or other white blood cells.

A "coding sequence", or a sequence which "encodes" a polypeptide, is a nucleic acid molecule which is transcribed (in the case of DNA) and translated (in the case of mRNA) into a polypeptide *in vivo* when placed under the control of appropriate regulatory sequences. The boundaries of the coding sequence are determined by a start codon at the 5' (amino) terminus and a translation stop codon at the 3' (carboxy) terminus. For the purposes of the invention, a coding sequence can include, but is not limited to, cDNA from viral, prokaryotic or eukaryotic mRNA, genomic DNA sequences from viral or prokaryotic DNA, and even synthetic DNA sequences. A transcription termination sequence may be located 3' to the coding sequence.

A "nucleic acid" molecule can include, but is not limited to, prokaryotic sequences, eukaryotic mRNA, cDNA from eukaryotic mRNA, genomic DNA sequences from eukaryotic (e.g., mammalian) DNA, and even synthetic DNA sequences. The term also captures sequences that include any of the known base analogs of DNA and RNA.

"Operably linked" refers to an arrangement of elements wherein the components so described are configured so as to perform their usual function. Thus, a given promoter operably linked to a coding sequence is capable of effecting the expression of the coding sequence when the proper enzymes are present. The promoter need not be contiguous with the coding sequence, so long as it functions to direct the expression thereof. Thus, for example, intervening untranslated yet transcribed sequences can be present between the promoter sequence and the coding sequence and the promoter sequence can still be considered "operably linked" to the coding sequence.

"Recombinant" as used herein to describe a nucleic acid molecule means a polynucleotide of genomic, cDNA, semisynthetic, or synthetic origin which, by virtue of its origin or manipulation: (1) is not associated with all or a portion of the polynucleotide with which it is associated in nature; and/or (2) is linked to a polynucleotide other than that to which it is linked in nature.

Two nucleic acid sequences are "substantially homologous" when at least about 70%, preferably at least about 80-90%, and most preferably at least about 95%,

-9-

of the nucleotides match over a defined length of the molecule. As used herein, substantially homologous also refers to sequences showing identity to the specified nucleic acid. Nucleic acid sequences that are substantially homologous can be identified in a Southern hybridization experiment under, for example, stringent
5 conditions, as defined for that particular system. Defining appropriate hybridization conditions is within the skill of the art. See, e.g., Sambrook et al., *supra*; *DNA Cloning*, vols I & II, *supra*; *Nucleic Acid Hybridization*, *supra*. Such sequences can also be confirmed and further characterized by direct sequencing of PCR products.

The terms "individual" and "subject" are used interchangeably herein to refer
10 to any member of the subphylum cordata, including, without limitation, humans and other primates, including non-human primates such as chimpanzees and other apes and monkey species; farm animals such as cattle, sheep, pigs, goats and horses; domestic mammals such as dogs and cats; laboratory animals including rodents such as mice, rats and guinea pigs; birds, including domestic, wild and game birds such as
15 chickens, turkeys and other gallinaceous birds, ducks, geese, and the like. The terms do not denote a particular age. Thus, both adult and newborn individuals are intended to be covered. The methods described herein are intended for use in any of the above vertebrate species, since the immune systems of all of these vertebrates operate similarly.
20

B. General Methods

A minimal promoter is used in the present invention. The minimal promoter sequence is generally derived from a DNA virus. Typically, the promoter is a promoter which is associated with an early viral gene and usually modulated by an
25 upstream or downstream enhancer element. The promoter sequence is used in its enhancerless form (i.e., it is not coupled with its native enhancer sequence when used in the context of the present invention, however, it may be used in a construct which contains other heterologous enhancer sequences). Thus, the minimal promoters of the present invention will typically be comprised of a nucleotide sequence of about
30 130 bases or less, which sequence will correspond to the sequence spanning positions -1 to about -130 relative to the start of RNA synthesis of the native viral early gene.

In preferred embodiments, the minimal promoter is obtained or derived from

-10-

a member of the Herpesvirus family of viruses. In particular embodiments, the minimal promoter consists essentially of an enhancerless promoter sequence from a simian, murine or human CMV virus (for example, the sCMV or hCMV immediate early promoter), an enhancerless promoter sequence from a RSV virus, an
5 enhancerless promoter sequence from a pseudorabies virus (PRV) such as the PRV early promoter region, or a functional variant thereof. The minimal promoter sequence may therefore consist essentially of a human cytomegalovirus (hCMV) immediate early promoter sequence, a pseudorabies virus (PRV) early promoter region, a simian cytomegalovirus (sCMV) immediate early promoter sequence or a
10 functional variant thereof.

A functional variant sequence may vary from a native promoter sequence by one or more base substitutions, deletions or insertions. There may be from 1 to 30, for example from 5 to 20, base substitutions and/or from 1 to 30, for example from 5 to 20, base deletions and/or from 1 to 30, for example 5 to 20, base insertions.
15 Functional fragments of a native promoter sequence may be used.

Variant sequences can readily be constructed by routine methodologies such as site-directed mutagenesis. The ability of a variant sequence to act as a promoter and thus retain function can be determined by experimentation. A variant sequence can be coupled to a reporter gene in a suitable expression system and the presence or
20 absence of expression determined. The present invention is particularly applicable to humans, so the ability of a variant sequence to drive expression *in vitro* in a human cell line may be examined.

The minimal promoter sequence is coupled with a heterologous nucleotide sequence of interest, typically a full gene when used in the context of gene therapy or
25 a coding sequence for an antigen when used in the context of nucleic acid immunization. In the case of gene therapy, the nucleotide sequence of interest encodes a protein whose expression confers benefits on the subject under treatment. A genetic defect can thus be compensated for. The coding sequence may encode a therapeutic protein.

30 The protein may be a blood protein, such as a clotting protein (e.g. kinogen, prothrombin, fibrinogen factor VII, factor VIII or factor IX). The protein may be an enzyme, such as a catabolic or anabolic enzyme. The enzyme may be a gastro-

-11-

intestinal enzyme, metabolic (e.g. glycolysis or Krebs cycle) enzyme or a cell signalling enzyme . The enzyme may make, breakdown or modify lipids, fatty acids, glycogen, amino acids, proteins, nucleotides, polynucleotides (e.g. DNA or RNA) or carbohydrate (e.g. sugars), and thus may typically be a protease, lipase or 5 carbohydrase. The enzyme may be a protein modifying enzyme, such as an enzyme that adds or takes chemical moieties from a protein (e.g. a kinase or phosphatase).

The protein may be a transport or binding protein (e.g. which binds and/or transports a vitamin, metal ion, amino acid or lipid, such as cholesterol ester transfer protein, phospholipid transfer protein or an HDL binding protein). The protein may 10 be a connective tissue protein (e.g. a collagen, elastin or fibronectin), or a muscle protein (e.g. actin, myosin, dystrophin or mini-dystrophin). The protein may be a neuronal, liver, cardiac or adipocyte protein. The protein may be cytotoxic. The protein may be a cytochrome.

The protein may be able to cause the replication, growth or differentiation of 15 cells. The protein may be development gene (e.g. which is expressed only before birth). The protein may be aid transcription or translation gene or may regulate transcription or translation (e.g. a transcription factor or a protein that binds a transcription factor or polymerase). The protein may be a signalling molecule, such as an intracellular or extracellular signalling molecule (e.g. a hormone).

20 The protein may be an immune system gene, such as an antibody, T cell receptor, MHC molecule, cytokine (e.g IL-1, IL-2, IL-3, IL-4, IL-5, IL-6, IL-7, IL-8, IL-10, IL-10, TNF- α , TNF- β , TGF- β), an interferon (e.g. IFN- α , IFN- β , IFN- γ), chemokine (e.g. MIP-1 α , MIP-1 β , RANTES), an immune receptor (e.g. a receptor for a cytokine, interferon or chemokine, such as receptor for any of the above- 25 mentioned cytokines, interferons or chemokines), a cell surface marker (e.g. macrophage, T cell, B cell, NK cell or dendritic cell surface marker)(eg. CD 1, 2, 3, 4, 5, 6, 7, 8, , 16, 18, , 19, 28, 40, or 45; or a natural ligand thereof) or a complement gene.

The protein may be a trophic factor (e.g. BDNF, CNTF, NGF, IGF, GMF, 30 aFGF, bFGF, VEGF, NT3, T5, HARP) or an apolipoprotein. The protein may be a tumour suppressor genes (e.g. p53, Rb, Rap1A, DCC or k-rev) or a suicide gene (thymidine kinase or cytosine deaminase).

-12-

When used in reagents for nucleic acid immunization, the minimal promoter will be operably linked to a coding sequence which encodes an antigen of interest. The antigen of interest will preferably be associated with a pathogen, such as a viral, bacterial or parasitic pathogen, or the antigen may be a tumor-specific antigen. The 5 antigen may be a full length protein. Alternatively, the antigen may just consist essentially of a B-cell epitope or a T-cell epitope of an antigen.

Tumor-specific antigens include, but are not limited to, any of the various MAGEs (melanoma associated antigen E), including MAGE 1, MAGE 2, MAGE 3 (HLA-A1 peptide), MAGE 4, etc.; any of the various tyrosinases (HLA-A2 peptide); 10 mutant ras; mutant p53; and p97 melanoma antigen. Other tumor-specific antigens include the Ras peptide and p53 peptide associated with advanced cancers, the HPV 16/18 and E6/E7 antigens associated with cervical cancers, MUC1-KLH antigen associated with breast carcinoma, CEA (carcinoembryonic antigen) associated with colorectal cancer, gp100 or MART1 antigens associated with melanoma, and the 15 PSA antigen associated with prostate cancer. The *p53* gene sequence is known (see e.g., Harris et al. (1986) *Mol. Cell. Biol.* 6:4650-4656) and is deposited with GenBank under Accession No. M14694.

Suitable viral antigens include, but are not limited to, polynucleotide sequences encoding antigens from the hepatitis family of viruses, including hepatitis 20 A virus (HAV), hepatitis B virus (HBV), hepatitis C virus (HCV), the delta hepatitis virus (HDV), hepatitis E virus (HEV) and hepatitis G virus (HGV). By way of example, the viral genomic sequence of HBV is known, as are methods for obtaining antigen-encoding sequences therefrom. See, e.g., Ganem et al. (1987) *Annu. Rev. Biochem.* 56:651-693; Hollinger, F.B. (1990) *Hepatitis B virus*, vol. II, pp.2171-2235, in Fields et al. (eds), Virology, 2nd ed, Raven Press, New York, NY; and Valenzuela et al. (1980) *The nucleotide Sequence of the Hepatitis B viral Genome and the Identification of the Major Viral Genes*, pp. 57-70, in Fields et al. (eds), Animal Virus Genetics, Academic Press, New York, NY). The HBV genome encodes several viral proteins, including the large, middle and major surface antigen 25 30 polypeptides, the X-gene polypeptide, and the core polypeptide. See, e.g., Yokosuka et al. (1986) *N. Engl. J. Med.* 315:1187-1192; Imazeki et al. (1987) *Hepatology* 7:753-757; Kaneko et al. (1988) *J. Virol.* 62:3979-3984; and Ou et al. (1990) *J.*

-13-

Virol. 64:4578-4581. In like manner, the viral genomic sequence of HCV is known, as are methods for obtaining the sequence. See, e.g., International Publication Nos. WO 89/04669; WO 90/11089; and WO 90/14436. The HCV genome encodes several viral proteins, including E1 and E2. See, e.g., Houghton et al. (1991)

5 *Hepatology* 14:381-388. The sequences encoding these HBV and HCV proteins, as well as antigenic fragments thereof, will find use in the present methods. Similarly, the coding sequence for the δ-antigen from HDV is known (see, e.g., U.S. Patent No. 5,378,814).

In like manner, sequences encoding a wide variety of protein antigens from
10 the herpesvirus family can be used in the present invention, including antigens derived from herpes simplex virus (HSV) types 1 and 2, such as HSV-1 and HSV-2 glycoproteins gB, gD and gH; antigens from varicella zoster virus (VZV), Epstein-Barr virus (EBV) and cytomegalovirus (CMV) including CMV gB and gH; and antigens from other human herpesviruses such as HHV6 and HHV7. (See, e.g. Chee
15 et al. (1990) *Cytomegaloviruses* (J.K. McDougall, ed., Springer-Verlag, pp. 125-169; McGeoch et al. (1988) *J. Gen. Virol.* 69:1531-1574; U.S. Patent No. 5,171,568; Baer et al. (1984) *Nature* 310:207-211; and Davison et al. (1986) *J. Gen. Virol.* 67:1759-1816.)

HIV antigens, such as the gp120 sequences for a multitude of HIV-1 and
20 HIV-2 isolates, including members of the various genetic subtypes of HIV, are known and reported (see, e.g., Myers et al., Los Alamos Database, Los Alamos National Laboratory, Los Alamos, New Mexico (1992); and Modrow et al. (1987) *J. Virol.* 61:570-578) and antigens derived from any of these isolates will find use in the present methods. Furthermore, the invention is equally applicable to other
25 immunogenic moieties derived from any of the various HIV isolates, including any of the various envelope proteins such as gp160 and gp41, gag antigens such as p24gag and p55gag, as well as proteins derived from the *pol*, *env*, *tat*, *vif*, *rev*, *nef*, *vpr*, *vpu* and LTR regions of HIV.

Sequences encoding antigens derived or obtained from other viruses will also
30 find use in the claimed methods, such as without limitation, sequences from members of the families Picornaviridae (e.g., polioviruses, etc.); Caliciviridae; Togaviridae (e.g., rubella virus, dengue virus, etc.); Flaviviridae; Coronaviridae;

-14-

Reoviridae; Birnaviridae; Rhabdoviridae (e.g., rabies virus, etc.); Filoviridae; Paramyxoviridae (e.g., mumps virus, measles virus, respiratory syncytial virus, etc.); Bunyaviridae; Arenaviridae; Retroviridae (e.g., HTLV-I; HTLV-II; HIV-1 (also known as HTLV-III, LAV, ARV, hTLR, etc.)), including but not limited to antigens 5 from the isolates HIV_{IIIb}, HIV_{SF2}, HIV_{LAV}, HIV_{LA1}, HIV_{MN}); HIV-1_{CM235}, HIV-1_{US4}; HIV-2, among others. See, e.g. *Virology*, 3rd Edition (W.K. Joklik ed. 1988); *Fundamental Virology*, 2nd Edition (B.N. Fields and D.M. Knipe, eds. 1991), for a description of these and other viruses.

Sequences encoding suitable bacterial and parasitic antigens are obtained or 10 derived from known causative agents responsible for diseases such as Diphteria, Pertussis, Tetanus, Tuberculosis, Bacterial or Fungal Pneumonia, Cholera, Typhoid, Plague, Shigellosis or Salmonellosis, Legionaire's Disease, Lyme Disease, Leprosy, Malaria, Hookworm, Onchocerciasis, Schistosomiasis, Trypanasomiasis, Lesmaniasis, Giardia, Amoebiasis, Filariasis, Borelia, and Trichinosis. Still further 15 antigens can be obtained or derived from unconventional viruses or virus-like agents such as the causative agents of kuru, Creutzfeldt-Jakob disease (CJD), scrapie, transmissible mink encephalopathy, and chronic wasting diseases, or from proteinaceous infectious particles such as prions that are associated with mad cow disease.

Both the sequence for the minimal promoter and the coding sequence of 20 interest can be obtained and/or prepared using known methods. For example, substantially pure antigen preparations can be obtained using standard molecular biological tools. That is, polynucleotide sequences coding for the above-described antigens can be obtained using recombinant methods, such as by screening cDNA 25 and genomic libraries from cells expressing the gene, or by deriving the gene from a vector known to include the same. Furthermore, the desired gene or promoter sequence can be isolated directly from cells and tissues containing the same, using standard techniques, such as phenol extraction and PCR of cDNA or genomic DNA. See, e.g., Sambrook et al., *supra*, for a description of techniques used to obtain and 30 isolate DNA. Polynucleotide sequences can also be produced synthetically, rather than cloned.

Yet another convenient method for isolating specific nucleic acid molecules

-15-

is by the polymerase chain reaction (PCR). Mullis et al. (1987) *Methods Enzymol.* 155:335-350. This technique uses DNA polymerase, usually a thermostable DNA polymerase, to replicate a desired region of DNA. The region of DNA to be replicated is identified by oligonucleotides of specified sequence complementary to 5 opposite ends and opposite strands of the desired DNA to prime the replication reaction. The product of the first round of replication is itself a template for subsequent replication, thus repeated successive cycles of replication result in geometric amplification of the DNA fragment delimited by the primer pair used.

Once the sequences for the minimal promoter and the coding sequence of 10 interest have been obtained, they are operably linked together to provide a nucleic acid molecule using standard cloning or molecular biology techniques. See, e.g., Edge (1981) *Nature* 292:756; Nambair et al (1984) *Science* 223:1299; and Jay et al 91984) *J. Biol. Chem.* 259:6311. The nucleic acid molecule is then inserted into a suitable vector such as an expression plasmid or viral vector construct.

15 The nucleic acid construct comprising the minimal promoter and a selected coding sequence generally also comprises other control sequences. These other control sequences typically comprise a terminator and/or translation initiation sequence (e.g. GCCACCATGG or GCCCCCATGG) and/or translational stop codon (e.g. TAA, TAG or TGA) and/or polyadenylation signal and/or a RNA pause site.
20 The native enhancer for the promoter sequence is not present, however. Generally, no enhancer is present at all.

For gene therapy purposes, the nucleic acid construct is integrated into the genome of the cell into which it has been introduced. The nucleic acid construct may therefore also comprise a sequence which enhances integration of the construct, such 25 as the loxP sites of the bacteriophage P1 Cre recombination system, FRT sites of the yeast FLP recombination system or Adeno-associated virus (AAV) terminal repeat sequences.

Once complete, the constructs are used for gene therapy or nucleic acid immunization using standard gene delivery protocols. Methods for gene delivery are 30 known in the art. See, e.g., U.S. Patent Nos. 5,399,346, 5,580,859, 5,589,466. Genes can be delivered either directly to a subject or, alternatively, delivered *ex vivo*, to cells derived from the subject and the cells reimplanted in the subject.

-16-

A number of viral based systems have been developed for gene transfer into mammalian cells. For example, a selected coding sequence can be inserted into a vector and packaged in retroviral particles using techniques known in the art. The recombinant virus can then be isolated and delivered to cells of the subject either *in vivo* or *ex vivo*. A number of retroviral systems have been described (U.S. Patent No. 5,219,740; Miller et al. (1989) *BioTechniques* 7:980-990; Miller, A.D. (1990) *Human Gene Therapy* 1:5-14; and Burns et al. (1993) *Proc. Natl. Acad. Sci. USA* 90:8033-8037.

A number of adenovirus vectors have also been described (Haj-Ahmad et al. 10 (1986) *J. Virol.* 57:267-274; Bett et al. (1993) *J. Virol.* 67:5911-5921; Mittereder et al. (1994) *Human Gene Therapy* 5:717-729; and Rich et al. (1993) *Human Gene Therapy* 4:461-476). Additionally, various adeno-associated virus (AAV) vector systems have been developed for gene delivery. AAV vectors can be readily constructed using techniques well known in the art. See, e.g., U.S. Patent Nos. 15 5,173,414 and 5,139,941; International Publication Nos. WO 92/01070 (published 23 January 1992) and WO 93/03769 (published 4 March 1993); Lebkowski et al. (1988) *Molec. Cell. Biol.* 8:3988-3996; Vincent et al. (1990) *Vaccines 90* (Cold Spring Harbor Laboratory Press); Carter, B.J. (1992) *Current Opinion in Biotechnology* 3:533-539; Muzyczka, N. (1992) *Current Topics in Microbiol. and Immunol.* 158:97-20 129; and Kotin, R.M. (1994) *Human Gene Therapy* 5:793-801. Additional viral vectors which will find use for delivering the nucleic acid molecules encoding the antigens of interest include those derived from the pox family of viruses, including vaccinia virus and avian poxvirus.

If viral vectors are not wanted, liposomal preparations can alternatively be 25 used to deliver the nucleic acid molecules of the invention. Useful liposomal preparations include cationic (positively charged), anionic (negatively charged) and neutral preparations, with cationic liposomes particularly preferred. Cationic liposomes have been shown to mediate intracellular delivery of plasmid DNA (Felgner et al. (1987) *Proc. Natl. Acad. Sci. USA* 84:7413-7416) and mRNA (Malone 30 et al. (1989) *Proc. Natl. Acad. Sci. USA* 86:6077-6081).

As yet another alternative to viral vector systems, the nucleic acid molecules of the present invention may be encapsulated, adsorbed to, or associated with,

-17-

particulate carriers. Suitable particulate carriers include those derived from polymethyl methacrylate polymers, as well as PLG microparticles derived from poly(lactides) and poly(lactide-co-glycolides). See, e.g., Jeffery et al. (1993) *Pharm. Res.* 10:362-368. Other particulate systems and polymers can also be used, for 5 example, polymers such as polylysine, polyarginine, polyornithine, spermine, spermidine, as well as conjugates of these molecules.

Formulation of a composition comprising the above nucleic acid molecules can be carried out using standard pharmaceutical formulation chemistries and methodologies all of which are readily available to the reasonably skilled artisan.

10 For example, compositions containing one or more nucleic acid molecules can be combined with one or more pharmaceutically acceptable excipients or vehicles. Auxiliary substances, such as wetting or emulsifying agents, pH buffering substances and the like, may be present in the excipient or vehicle. These excipients, vehicles and auxiliary substances are generally pharmaceutical agents that do not induce an 15 immune response in the individual receiving the composition, and which may be administered without undue toxicity. Pharmaceutically acceptable excipients include, but are not limited to, liquids such as water, saline, polyethyleneglycol, hyaluronic acid, glycerol and ethanol. Pharmaceutically acceptable salts can also be included therein, for example, mineral acid salts such as hydrochlorides,

20 hydrobromides, phosphates, sulfates, and the like; and the salts of organic acids such as acetates, propionates, malonates, benzoates, and the like. Certain facilitators of nucleic acid uptake and/or expression can also be included in the compositions, for example, facilitators such as bupivacaine, cardiotoxin and sucrose. A thorough discussion of pharmaceutically acceptable excipients, vehicles and auxiliary 25 substances is available in REMINGTON'S PHARMACEUTICAL SCIENCES (Mack Pub. Co., N.J. 1991), incorporated herein by reference.

When used in nucleic acid immunizations, the formulated compositions will include an amount of the antigen of interest which is sufficient to mount an immunological response, as defined above. An appropriate effective amount can be 30 readily determined by one of skill in the art. Such an amount will fall in a relatively broad range that can be determined through routine trials. The compositions may contain from about 0.1% to about 99.9% of the antigen and can be administered

-18-

directly to the subject or, alternatively, delivered *ex vivo*, to cells derived from the subject, using methods known to those skilled in the art. For example, methods for the *ex vivo* delivery and reimplantation of transformed cells into a subject are known (e.g., dextran-mediated transfection, calcium phosphate precipitation,

5 electroporation, and direct microinjection into nuclei). Methods for *in vivo* delivery can entail injection using a conventional syringe. The constructs can be injected either subcutaneously, epidermally, intradermally, intramucosally such as nasally, rectally and vaginally, intraperitoneally, intravenously, orally or intramuscularly.

Other modes of administration include oral and pulmonary administration,

10 suppositories, and transdermal applications.

It is preferred, however, that the nucleic acid molecules be delivered using a particle acceleration device which fires nucleic acid-coated microparticles into target tissue, or transdermally delivers particulate nucleic acid compositions. In this regard, particle-mediated (sometimes referred to as "gene gun") nucleic acid immunization

15 has been shown to elicit both humoral and cytotoxic T lymphocyte immune responses following epidermal delivery of nanogram quantities of DNA. Pertmer et al. (1995) *Vaccine* 13:1427-1430. Particle-mediated delivery techniques have been compared to other types of nucleic acid inoculation, and found markedly superior. Fynan et al. (1995) *Int. J. Immunopharmacology* 17:79-83, Fynan et al. (1993) *Proc.*

20 *Natl. Acad. Sci. USA* 90:11478-11482, and Raz et al. (1994) *Proc. Natl. Acad. Sci. USA* 91:9519-9523. Such studies have investigated particle-mediated delivery of nucleic acid-based vaccines to both superficial skin and muscle tissue.

Particle-mediated methods for delivering nucleic acid preparations are known in the art. Thus, once prepared and suitably purified, the above-described nucleic acid molecules can be coated onto carrier particles using a variety of techniques known in the art. Carrier particles are selected from materials which have a suitable density in the range of particle sizes typically used for intracellular delivery from a gene gun device. The optimum carrier particle size will, of course, depend on the diameter of the target cells.

30 For the purposes of the invention, tungsten, gold, platinum and iridium carrier particles can be used. Tungsten and gold particles are preferred. Tungsten particles are readily available in average sizes of 0.5 to 2.0 μm in diameter. Gold particles or

-19-

microcrystalline gold (e.g., gold powder A1570, available from Engelhard Corp., East Newark, NJ) will also find use with the present invention. Gold particles provide uniformity in size (available from Alpha Chemicals in particle sizes of 1-3 μm , or available from Degussa, South Plainfield, NJ in a range of particle sizes 5 including 0.95 μm). Microcrystalline gold provides a diverse particle size distribution, typically in the range of 0.5-5 μm . However, the irregular surface area of microcrystalline gold provides for highly efficient coating with nucleic acids.

A number of methods are known and have been described for coating or precipitating DNA or RNA onto gold or tungsten particles. Most such methods 10 generally combine a predetermined amount of gold or tungsten with plasmid DNA, CaCl_2 and spermidine. The resulting solution is vortexed continually during the coating procedure to ensure uniformity of the reaction mixture. After precipitation of the nucleic acid, the coated particles can be transferred to suitable membranes and allowed to dry prior to use, coated onto surfaces of a sample module or cassette, or 15 loaded into a delivery cassette for use in particular gene gun instruments.

Various particle acceleration devices suitable for particle-mediated delivery are known in the art, and are all suited for use in the practice of the invention. Current device designs employ an explosive, electric or gaseous discharge to propel the coated carrier particles toward target cells. The coated carrier particles can 20 themselves be releasably attached to a movable carrier sheet, or removably attached to a surface along which a gas stream passes, lifting the particles from the surface and accelerating them toward the target. An example of a gaseous discharge device is described in U.S. Patent No. 5,204,253. An explosive-type device is described in U.S. Patent No. 4,945,050. One example of a helium discharge-type particle 25 acceleration apparatus is the PowderJect XR[®] instrument (PowderJect Vaccines, Inc., Madison), WI, which instrument is described in U.S. Patent No. 5,120,657. An electric discharge apparatus suitable for use herein is described in U.S. Patent No. 5,149,655. The disclosure of all of these patents is incorporated herein by reference.

The particulate nucleic acid compositions can alternatively be administered 30 transdermally using a needleless syringe device. For example, a particulate composition comprising the nucleic acid constructs of the present invention can be obtained using general pharmaceutical methods such as simple evaporation

-20-

(crystallization), vacuum drying, spray drying or lyophilization. If desired, the particles can be further densified using the techniques described in commonly owned International Publication No. WO 97/48485, incorporated herein by reference. These particulate compositions can then be delivered from a needleless syringe system such 5 as those described in commonly owned International Publication Nos. WO 94/24263, WO 96/04947, WO 96/12513, and WO 96/20022, all of which are incorporated herein by reference.

The particle compositions or coated particles are administered to the individual in a manner compatible with the dosage formulation, and in an amount 10 that will be effective for the purposes of the invention. The amount of the composition to be delivered depends on the individual to be tested. The exact amount necessary will vary depending on the age and general condition of the individual to be treated, and an appropriate effective amount can be readily determined by one of skill in the art upon reading the instant specification.

15

C. Experimental

Below are examples of specific embodiments for carrying out the present invention. The examples are offered for illustrative purposes only, and are not intended to limit the scope of the present invention in any way.

20 Efforts have been made to ensure accuracy with respect to numbers used (e.g., amounts, temperatures, etc.), but some experimental error and deviation should, of course, be allowed for.

Example 1

25

A number of expression systems were constructed to compare antigen expression from vectors containing an antigen coding sequence under transcriptional control of an enhanced promoter and the corresponding minimal promoter (using *in vitro* expression testing methods). The immunogenicity of the same vector 30 constructs was then assessed (ability to elicit an antibody response against the antigen) using *in vivo* nucleic acid immunization testing methods.

Particularly, vectors containing the simian CMV promoter with ("sCMV")

-21-

and without ("mP-sCMV") its enhancer, vectors containing the human CMV immediate early promoter with ("CMV") and without ("mp" or "mP-CMV") its enhancer, and vectors containing the PRV promoter with ("PRV") and without ("mP-PRV") its enhancer were assessed for both antigen production (*in vitro* expression) 5 and for antibody production (*in vivo* immunogenicity). The results are depicted in the attached figure. In all cases, removal of the enhancer sequences reduced expression levels from the minimal promoter constructs (relative to the enhanced promoters) (not shown). However, as can be seen in the figure, the minimal promoter constructs provided for dramatically increased antibody production 10 (relative to the enhanced promoters) in the *in vivo* component of the study

Example 2

In order to further assess the effect of using an enhancer-less promoter system 15 in a nucleic acid immunization protocol, a number of experiments were carried out to compare the immunogenicity of antigen constructs containing full-length (enhanced) promoter systems and the minimal (enhancer-less) promoter systems of the present invention.

More particularly, a series of Hepatitis B surface antigen (HBsAg) constructs 20 were constructed as follows. To generate the HBsAg coding region, the pAM6 construct (obtained from the American Type Culture Collection "ATCC") was cut with *Nco*1 and treated with mung bean nuclease to remove the start codon of the X- antigen. The resultant DNA was then cut with *Bam*H1 and treated with T4 DNA polymerase to blunt-end the DNA and create an HBsAg expression cassette. The 25 HBsAg expression cassette is present in the 1.2 kB fragment. The plasmid construct PJV7077 (Schmaljohn et al. (1997) *J. Virol.* 71:9563-9569) which contains the full-length human CMV (Towne strain) immediate early promoter (with enhancer) was cut with *Hind*3 and *Bgl*2, and then treated with T4 DNA polymerase and calf-alkaline phosphatase to create blunt-ended DNA adjacent.

30 The PJV7232 host plasmid (a derivative of the PJV7077 construct described above) contains a promoter insertion region flanked by a *Sal*1 and *Bam*H1 site. New promoters were PCR'd out of viral stocks, infected cells, plasmids, etc., using

-22-

primers homologous to the promoter region of interest. These primers were designed with *SalI* and *BamH*1 restriction sites at the terminal ends such that the PCR fragment can be cut with these enzymes to facilitate ready insertion into the similarly cut PJV7232 construct. This method was then used to construct HBsAg expression 5 cassettes driven by full-length (enhanced) simian CMV (sCMV) and pseudorabies virus (PRV) promoter systems. All PCR reactions were carried out under standard conditions to amplify the promoter elements from the target sequences according to manufacturer instructions, particularly:

1x PCR core buffer w/ 15mM MgCl₂;

10 0.4 μM each of sense and antisense primers;

200 μM of each dNTP;

2.5 μg Taq polymerase;

0.1-1.0 μg target sample (ATCC# VR706 for sCMV and ATCC# VR135 for PRV);

15 water to 100 μL; and

mineral oil overlay.

the thermocycler was programmed to run the following routine:

4 minutes at 95°C;

20 30 cycles of (1 minute at 95° + 1 min.15 sec. at 55°C + 1 min. at 72°C);

10 minutes at 72°C; and

4°C hold.

After theromcycling was completed, the Taq polymerase was removed by 25 phenol/chloroform extraction and ethanol precipitation of the PCR products. This amplified DNA, as well as the PJV7232 construct were then cut with the *SalI* and *BamH*1 restriction enzymes.

After being cut with the appropriate restriction enzymes (and blunt-ended if needed), the DNAs were run on an agarose gel to separate, purify and isolate DNA 30 bands of interest. These isolated bands were then mixed together in a ligase reaction and incubated overnight at 16°C. The ligation reactions were transformed into *E.coli* cells. The cut PJV7077 or PJV7232 constructs are not able to grow in the bacterial

-23-

host cells under antibiotic selection unless they contain an appropriate insert fragment. Accordingly, bacterial colonies containing the new recombinant DNA constructs (the HbsAG sequence promoted by a full length hCMV, sCMV or PRV promoter) were grown on an agar plate, and the DNA was isolated from these 5 colonies. The DNA was analysed for proper ligation of the various fragments. Bacterial isolates which harbor correct ligation products were amplified in a large liquid culture, on which a large-scale DNA extraction was performed. The resultant DNA is then used as a vaccine lot

In order to make corresponding minimal promoter (enhancer-less) versions of 10 the above-described hCMV-sAG, sCMV-sAG and PRV-sAG constructs, the DNAs were cut with restriction enzyme pairs (*Sal*1/*Bam*1, *Sal*1/*Sca*1, or *Sal*1/*Not*1, respectively). The cut DNA was treated with T4 DNA polymerase to create blunt-ended DNA. The blunt-ended DNA was self-ligated, transformed, analyzed and amplified using the same conditions set forth herein above. This procedure produced 15 vaccine lots were at least the majority of each enhancer sequence was deleted from the promoter.

The DNA vaccine products were then coated onto gold carrier particles and administered to murine subjects using a particle-mediated delivery technique. Specifically, for each plasmid DNA construct to be tested, 25 mg of 2 µm gold 20 powder was weighed into a microfuge tube. After addition of a 250 µL aliquot of 50 mM spermidine (Aldrich), the tubes were vortexed and briefly sonicated. The gold was then microfuged out, and the spermidine replaced by a fresh 100 µL aliquot. The gold was then resuspended by vortexing, after which 25 µg of DNA was added to the tubes and mixed. While the tube is lightly vortexed, 100 µL of 10% CaCl 25 (Fujisawa) USA, Inc.) was added to precipitate the DNA onto the gold beads. The precipitation reaction was allowed to proceed for ten minutes on the benchtop, after which the gold was collected by a brief microfuge spin and washed three times with absolute ethanol (Spectrum) to remove excess precipitation reagents. The washed gold/DNA complex was then resuspended with 0.05 mg/mL polyvinylpyrrolidone 30 (360 kD, Spectrum) in absolute ethanol. The resultant slurry was then injected into a TEFZEL® tube (McMaster-Carr) housed in a tube turner coating machine (PowderJect Vaccines, Inc., Madison WI) which coats the inside of the tube with the

-24-

gold/DNA complex. This tube turner machine is described in US Patent No. 5,733,600. After the coating procedure was completed, the tubes were cut into 0.5 inch "shots" which were loaded into a particle-mediated delivery device (the PowderJect XR1 device, PowderJect Vaccines, Inc., Madison, WI) for delivery into 5 the mice.

For the vaccination procedures, four- to six-week old Balb/c mice were anesthetized with a mixture of KETASET® (Fort Dodge) and ROMPUN® (Bayer) anesthetics. The bellies were shaved with a pair of electric clippers to remove hair, and two non-overlapping "shots" of vaccine were delivered from the PowderJect 10 XR1 device (at 450 psi) to the shaved area. The animals were returned to their cages for six weeks after which time blood samples were obtained for sera analysis of anti-HBsAg antibodies.

More particularly, blood samples were harvested from the vaccinated animals. Up to 200 µL aliquots of serum isolated from the blood samples were then 15 placed into wells of a reaction vessel supplied with the AUSAB® EIA Diagnostic Kit (Abbott Laboratories). The amount of sera added depended upon the antibody titer of the sample, and each sample was diluted with sample dilution buffer to fall within values that are readable by the immunoassay kit. 200 µL aliquots of standardization panel samples were added to the wells of the reaction vessel. A bead was added to 20 each well, after which the vessel was sealed and incubated for two hours at 40°C. The wells were then washed of all liquid reaction components. 200 µL aliquots of the conjugate mix was then added to each washed well, after which the vessel was sealed and incubated for two hours again at 40°C. The wells were then washed of all 25 liquid reaction components, and the bead transferred to new reaction tubes after which 300 µL of the color development buffer was added. After 30 minutes, the color development reaction was stopped by addition of 1M H₂SO₄, and the absorbance was measured at 490nm using a Quantum II™ spectrophotometer. The spectrophotometer was used to calculate antibody levels of each sample by comparison of the absorbance of the sample against a standard curve generated with 30 a standardization panel. The antibody levels were then corrected for any dilution factors, and the final data reported as the geometric mean titers of all animals vaccinated with a particular DNA vaccine construct.

-25-

The results of these studies are depicted in Figures 2-4. Figure 2 shows a comparison between the fully enhanced hCMV promoter system and the minimal hCMV promoter system of the present invention. As can be seen, the minimal promoter system gave an approximately three-fold improvement in antibody titer
5 over the fully enhanced promoter system (the results were pooled from four independent experiments of 8 mice per group). Figures 3 and 4 show similar results from comparisons between full-length (enhanced) promoters and their corresponding minimal (enhancer-less) promoter derivatives.

Accordingly, novel minimal promoter systems and nucleic acid reagents
10 comprising these systems have been described. Although preferred embodiments of the subject invention have been described in some detail, it is understood that obvious variations can be made without departing from the spirit and the scope of the invention as defined by the appended claims.

-26-

CLAIMS

1. Use of a nucleic acid construct comprising a minimal promoter sequence operably linked to a coding sequence encoding a polypeptide of interest in the manufacture of a medicament for use in obtaining expression in mammalian cells of the said polypeptide.
2. Use according to claim 1, wherein the coding sequence encodes an antigen and the medicament is for use in nucleic acid immunization.
3. Use according to claim 2, wherein the antigen is an antigen of a viral, bacterial, parasite or fungal pathogen.
- 10 4. Use according to claim 2, wherein the antigen is a tumor-specific antigen or an antigen associated with an autoimmune disease.
5. Use according to any one of claims 2 to 4, wherein the antigen comprises a B-cell epitope or a T-cell epitope.
- 15 6. Use according to any one of claims 2 to 5, wherein the nucleic acid construct is coated onto carrier particles.
7. Use according to claim 1, wherein the medicament is for use in gene therapy.
8. Use according to claim 7, wherein the nucleic acid construct is provided in a viral vector or liposomal preparation.
- 20 9. Use according to any one of the preceding claims, wherein the nucleic acid construct is DNA construct.
10. Use according to any one of the preceding claims, wherein the minimal promoter sequence consists essentially of a human cytomegalovirus (hCMV) immediate early promoter sequence, a pseudorabies virus (PRV) early promoter region, a simian cytomegalovirus (sCMV) immediate early promoter sequence or a functional variant thereof.
- 25 11. Use according to claim 10, wherein the minimal promoter sequence consists essentially of the sequence spanning positions 0 to -118 of the hCMV immediate early promoter region or a functional variant of the said spanning sequence.
- 30 12. A method of obtaining expression in mammalian cells of a polypeptide of interest, which method comprises transferring into said cells a nucleic

-27-

acid construct comprising a minimal promoter sequence operably linked to a coding sequence for the said polypeptide.

13. A method according to claim 12, wherein the construct is delivered directly into a subject.

5 14. A method according to claim 13, wherein the construct is delivered by injection, transdermal particle delivery, inhalation, topically, orally, intranasally or transmucosally.

15. A method according to claim 14, wherein the construct is delivered by needleless injection.

10 16. A method according to claim 12, wherein the construct is delivered *ex vivo* into cells taken from a subject and the cells are reintroduced into the subject.

17. A method according to any one of claims 13 to 16, wherein the subject is a human.

18. A method according to any one of claims 12 to 17, wherein the 15 polypeptide is an antigen.

19. A method according to claim 18, wherein the antigen is an antigen of a viral, bacterial, parasite or fungal pathogen.

20. A method according to claim 18, wherein the antigen is a tumor-specific antigen or an antigen associated with an autoimmune disease.

20 21. A method according to any one of claims 18 to 20, wherein the antigen comprises a B-cell epitope or a T-cell epitope.

22. A method according to any one of claims 12 to 21, wherein the nucleic acid construct is coated onto carrier particles.

23. A method according to any one of claims 12 to 22, wherein the 25 nucleic acid construct is a DNA construct.

24. A method according to any one of the preceding claims, wherein the minimal promoter sequence consists essentially of a human cytomegalovirus (hCMV) immediate early promoter sequence, a pseudorabies virus (PRV) early promoter region, a simian cytomegalovirus (sCMV) immediate early promoter sequence or a functional variant thereof.

30 25. A method according to claim 24, wherein the minimal promoter sequence consists essentially of the sequence spanning positions 0 to -118 of the

-28-

hCMV immediate early promoter region or a functional variant of the said spanning sequence.

26. Coated particles suitable for use in particle-mediated nucleic acid immunisation, which particles comprise carrier particles coated with a nucleic acid construct comprising a minimal promoter sequence operably linked to a coding sequence encoding an antigen.
 - 5 27. Coated particles according to claim 26, wherein the carrier particles are tungsten or gold particles.
 - 10 28. Coated particles according to claim 26 or 27, wherein the antigen is an antigen of a viral, bacterial, parasite or fungal pathogen.
 - 15 29. Coated particles according to claim 26 or 27, wherein the antigen is a tumor-specific antigen or an antigen associated with an autoimmune disease.
 30. Coated particles according to any one of claims 26 to 29, wherein the antigen comprises a B-cell epitope or a T-cell epitope.
 - 15 31. Coated particles according to any one of claims 26 to 30, wherein the nucleic acid construct is DNA construct.
 32. Coated particles according to any one of claims 26 to 31, wherein the minimal promoter sequence consists essentially of a human cytomegalovirus (hCMV) immediate early promoter sequence, a pseudorabies virus (PRV) early promoter region, a simian cytomegalovirus (sCMV) immediate early promoter sequence or a functional variant thereof.
 - 20 33. Coated particles according to claim 32, wherein the minimal promoter sequence consists essentially of the sequence spanning positions 0 to -118 of the hCMV immediate early promoter region or a functional variant of the said spanning sequence.
 - 25 34. A particle acceleration device suitable for particle-mediated nucleic acid immunisation, the said device being loaded with coated particles as defined in any one of claims 26 to 33.
 35. A purified, isolated minimal promoter sequence.
 - 30 36. A nucleic acid construct comprising a minimal promoter sequence operably linked to a coding sequence.
 37. A vector comprising the nucleic acid construct of claim 36.

-29-

38. A vector according to claim 37 which is a plasmid.

INTERNATIONAL SEARCH REPORT

International Application No
PCT/US 99/24694

A. CLASSIFICATION OF SUBJECT MATTER
 IPC 7 C12N15/12 A61K48/00 C12M1/00

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)
 IPC 7 A61K

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the International search (name of data base and, where practical, search terms used)

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X	<p>WO 98 20041 A (OKLAHOMA MED RES FOUND) 14 May 1998 (1998-05-14)</p> <p>page 2, line 7 -page 3, line 11 page 7 -page 8; example 1 figure 4 page 5, line 13 -page 6, line 28 page 7, line 4 - line 21; claims 1-3</p> <p style="text-align: center;">---</p> <p style="text-align: center;">-/-</p>	<p>1, 7-9, 12-17, 22, 23, 35-37</p>

Further documents are listed in the continuation of box C.

Patent family members are listed in annex.

* Special categories of cited documents :

- "A" document defining the general state of the art which is not considered to be of particular relevance
- "E" earlier document but published on or after the International filing date
- "L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- "O" document referring to an oral disclosure, use, exhibition or other means
- "P" document published prior to the International filing date but later than the priority date claimed

"T" later document published after the International filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.

"&" document member of the same patent family

INTERNATIONAL SEARCH REPORT

International application No.

PCT/US 99/24694

Box I Observations where certain claims were found unsearchable (Continuation of Item 1 of first sheet)

This International Search Report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. Claims Nos.:

because they relate to subject matter not required to be searched by this Authority, namely:

Remark: Although claims 13-17 completely, and 12, 18-25 partially, are directed to a method of treatment of the human/animal body, the search has been carried out and based on the alleged effects of the compound/composition.

2. Claims Nos.:

because they relate to parts of the International Application that do not comply with the prescribed requirements to such an extent that no meaningful International Search can be carried out, specifically:

3. Claims Nos.:

because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II Observations where unity of invention is lacking (Continuation of Item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

1. As all required additional search fees were timely paid by the applicant, this International Search Report covers all searchable claims.

2. As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.

3. As only some of the required additional search fees were timely paid by the applicant, this International Search Report covers only those claims for which fees were paid, specifically claims Nos.:

4. No required additional search fees were timely paid by the applicant. Consequently, this International Search Report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest

The additional search fees were accompanied by the applicant's protest.
 No protest accompanied the payment of additional search fees.
